Triangulations of root polytopes

Paola Cellini

Abstract. Let \( \Phi \) be an irreducible crystallographic root system and \( P \) its root polytope, i.e., the convex hull of \( \Phi \). We provide a uniform construction, for all root types, of a triangulation of the facets of \( P \). We also prove that, on each orbit of facets under the action of the Weyl group, the triangulation is unimodular with respect to a root sublattice that depends on the orbit.

1. Introduction

Let \( \Phi \) be an irreducible crystallographic root system in a Euclidean space \( E \), \( \Phi^+ \) a positive system of \( \Phi \), and \( W \) the Weyl group of \( \Phi \). Then, let \( P \) be the root polytope associated with \( \Phi \), i.e. the convex hull of all roots in \( \Phi \).

In [6], Marietti and the author have studied a natural set of representatives of the faces of \( P \) modulo the action of \( W \), the standard parabolic faces of \( P \). The set of all roots contained in a standard parabolic face is an abelian ideal of \( \Phi^+ \) (see Subsection 2.3 for a definition). We call face ideals or facet ideals the abelian ideals of \( \Phi^+ \) corresponding to the standard parabolic faces or facets of \( P \).

In [4], for \( \Phi \) of type \( A_n \) and \( C_n \), the same authors have constructed a triangulation of the standard parabolic facets whose simplexes have a natural interpretation in terms of the corresponding facet ideals. The construction is formally equal for both root types, though the proofs are distinct and based on the special combinatorics of these two root systems and their maximal abelian ideals. Through the action of \( W \), a triangulation of all the standard parabolic facets can be extended to a triangulation of the boundary of \( P \). Such an extension corresponds to an appropriate choice of representatives of the left cosets of \( W \) modulo the stabilizers of the standard parabolic facets. The triangulations of the boundary of \( P \) are also studied in [1] for all classical root types, using the coordinate description of \( \Phi \). In [12], the triangulations of the positive root polytope \( P^+ \), i.e. the convex hull of the positive roots and the origin, are studied for \( \Phi \) of type \( A_n \). The triangulations of \( P^+ \) are also studied in [18, 19] for \( A_n \) and \( C_n \).

In this paper, we give a uniform construction of a triangulation of the standard parabolic facets, for all finite irreducible crystallographic root systems. The construction coincides with the one of [4] for the types \( A_n \) and \( C_n \). We also obtain unimodularity results similar to those obtained for \( A_n \) and \( C_n \).

Keywords. Root system, root polytope, triangulation, Borel subalgebra, abelian ideal, abelian nilradical.
We need some preliminaries for describing the results in more detail. If \( \beta_1, \beta_2, \gamma_1, \gamma_2 \in \Phi^+ \) are such that \( \beta_1 + \beta_2 = \gamma_1 + \gamma_2 \), we say that \( \{ \beta_1, \beta_2 \} \) and \( \{ \gamma_1, \gamma_2 \} \) are crossing pairs. We first prove that if \( \{ \beta_1, \beta_2 \}, \{ \gamma_1, \gamma_2 \} \) are crossing pairs contained in a (common) abelian ideal, then, for all \( i, j \in \{ 1, 2 \} \), the differences \( \beta_i - \gamma_j \) are roots, in particular \( \beta_i \) and \( \gamma_j \) are comparable. This implies that the set \( \{ \beta_1, \beta_2, \gamma_1, \gamma_2 \} \) has a minimum and a maximum, more precisely, one of the two crossing pairs consists of these minimum and maximum, i.e., either \( \beta_1 < \gamma_i < \beta_2 \) for both \( i = 1 \) and \( 2 \), or the analogous relation with \( \beta \) and \( \gamma \) interchanged holds. We define the relations \( \preceq \) and \( \sim \) on \( \Phi^+ \) as follows. For all \( \beta_1, \beta_2 \in \Phi^+ \), we write \( \beta_1 \preceq \beta_2 \) if there exist \( \gamma_1, \gamma_2 \) such that \( \beta_1 + \beta_2 = \gamma_1 + \gamma_2 \) and \( \beta_1 < \gamma_1 < \beta_2 \) for both \( i = 1 \) and \( 2 \). Moreover, we write \( \beta_1 \sim \beta_2 \) if \( \beta_1 \preceq \beta_2 \) or \( \beta_2 \preceq \beta_1 \). Finally, we say that a subset \( R \) of \( \Phi^+ \) is reduced if \( \beta_1 \not\sim \beta_2 \) for all \( \beta_1, \beta_2 \in R \).

The first main result in this paper is that the maximal reduced subsets in a facet ideal provide a triangulation of the corresponding standard parabolic facet. For each standard parabolic facet \( F \) of \( \mathcal{P} \), let \( I_F \) be the corresponding facet ideal:

\[
I_F = F \cap \Phi,
\]

and

\[
T_F = \{ \text{Conv}(R) \mid R \subseteq I_F, \ R \text{ maximal reduced} \},
\]

where \( \text{Conv}(R) \) is the convex hull of \( R \). Then the following result holds.

**Theorem 1.1.** For each standard parabolic facet \( F \) of \( \mathcal{P} \), \( T_F \) is a triangulation of \( F \).

Clearly, the set of vertexes of the above triangulation is the set of all roots contained in \( F \).

Theorem 1.1 implies, in particular, that the maximal reduced subsets in \( I_F \) are linear bases of \( E \). Let \( \Pi \) and \( \theta \) be the simple system and the highest root of \( \Phi^+ \). Then, \( \{ -\theta \} \cup \Pi \) is the set of vertexes of the affine Dynkin diagram of \( \Phi \). For each \( \alpha \in \Pi \), let \( \Phi_\alpha \) and \( \widehat{\Phi_\alpha} \) be the root subsystems of \( \Phi \) generated by \( \Pi \setminus \{ \alpha \} \) and \( \{ -\theta \} \cup (\Pi \setminus \{ \alpha \}) \), respectively, and \( \Phi_\alpha^+ \) and \( \widehat{\Phi_\alpha^+} \) their positive systems contained in \( \Phi^+ \). Clearly, \( \widehat{\Phi_\alpha} \) has the same rank as \( \Phi \). We call the \( \widehat{\Phi_\alpha} \), for all \( \alpha \in \Pi \), the standard equal rank subsystems of \( \Phi \). The standard parabolic facets of \( \mathcal{P} \) naturally correspond to the irreducible standard equal rank root subsystems of \( \Phi \) [6]. Precisely, for each \( \alpha \in \Pi \) such that \( \widehat{\Phi_\alpha} \) is irreducible, let

\[
I_\alpha = \widehat{\Phi_\alpha^+} \setminus \Phi_\alpha.
\]

Then \( I_\alpha \) is a facet ideal of \( \Phi^+ \), and each facet ideal of \( \Phi^+ \) is obtained in this way (see Subsection 2.5). We prove the following result.

**Theorem 1.2.** Let \( \alpha \in \Pi \) be such that \( \widehat{\Phi_\alpha} \) is irreducible. Then, each maximal reduced subset contained in the facet ideal \( I_\alpha \) is a \( \mathbb{Z} \)-basis of the root lattice of \( \widehat{\Phi_\alpha} \). In particular, all the simplexes of the triangulation \( T_F \) have the same volume.

Part of the proofs require a case by case analysis. The cases to be considered can be restricted to a special, proper subset of facet ideals. Indeed, the results of [6] imply that the facet ideal \( I_\alpha \) (\( \alpha \in \Pi \), \( \widehat{\Phi_\alpha} \) irreducible), is an abelian nilradical (see Subsection 2.4) in the root subsystem \( \widehat{\Phi_\alpha^+} \). Hence, we may reduce to the case of abelian nilradicals.

The case by case analysis is contained in the proof of Proposition 5.11. This proof also provides an algorithm for the explicit computation of the triangulations for each root type, which will be done in a future paper.
2. Preliminaries

In this section we fix our main notation and recall some preliminary results. For the basic preliminary notions, we refer to [2] and [14] for root systems, and to [3] and [13] for Lie algebras.

2.1. Basic notation. General. We sometimes use the symbol := for emphasizing that equality holds by definition or that we are defining the left term of equality. We denote by E a Euclidean space, with scalar product $(\cdot, \cdot)$ and norm $|\cdot|$. We identify E with its dual space, through $(\cdot, \cdot)$. The null vector of E is denoted by 0. For any $S \subseteq E$, $\text{Span}(S)$ is the vector subspace generated by $S$ over $\mathbb{R}$ (the field of real numbers), and $\text{rk}(S) := \dim \text{Span}(S)$.

Root systems. We denote by $\Phi$ a reduced irreducible crystallographic root system in E and by $\Phi^+$ a fixed positive system of $\Phi$. The simple system of $\Phi$ corresponding to $\Phi^+$ is denoted by $\Pi$, while $\Omega^+$ is the set of fundamental co-weights of $\Phi$, i.e., the dual basis of $\Pi$ in E. For each $\alpha \in \Pi$, $\check{\omega}_\alpha$ is the fundamental co-weight defined by the conditions $(\alpha, \check{\omega}_\alpha) = 1$ and $(\alpha', \check{\omega}_\alpha) = 0$ for all $\alpha' \in \Pi \setminus \{\alpha\}$. For all $\alpha \in \Pi$ and $\beta \in \Phi$, we set $c_\alpha(\beta) = (\beta, \check{\omega}_\alpha)$, so that

$$\beta = \sum_{\alpha \in \Pi} c_\alpha(\beta) \alpha.$$ 

The support of $\beta$ is the set of simple roots with non-zero coefficient in the expression of $\beta$:

$$\text{Supp}(\beta) = \{\alpha \in \Pi \mid c_\alpha(\beta) \neq 0\}.$$ 

The highest root in $\Phi^+$ is denoted by $\theta$ and its coefficients with respect to $\Pi$ by $m_\alpha$, thus

$$\theta = \sum_{\alpha \in \Pi} m_\alpha \alpha.$$ 

We call $m_\alpha$ the multiplicity of $\alpha$ in $\Phi^+$.

For all $\beta \in \Phi$, $\beta^\vee$ is the corresponding coroot, i.e., $\beta^\vee = \frac{2\beta}{(\beta, \beta)}$.

For each root subsystem $\Psi$ of $\Phi$ we set $\Psi^+ = \Psi \cap \Phi^+$. It is well known that $\Psi^+$ is a positive system for $\Psi$: we call it the standard positive system of $\Psi$. Moreover, we denote by $L(\Psi)$ and $L^+(\Psi)$ the root lattice and positive root lattice of $\Psi$, i.e., the $\mathbb{Z}$-span of $\Psi$ and the $\mathbb{N}$-span of $\Psi^+$, respectively, where $\mathbb{Z}$ and $\mathbb{N}$ are the sets of integers and non-negative integers.

For any $S \subseteq \Phi$, we denote by $\Phi(S)$ the root subsystem of $\Phi$ generated by $S$, i.e., the minimal root system containing $S$, and we write $\Phi^+(S)$ for $\Phi(S)^+$. A root subsystem $\Psi$ of $\Phi$ is called parabolic if $\Psi = \Phi \cap \text{Span}(\Psi)$. For any linear subspace $H$ of $E$, the intersection $\Phi \cap H$ is a parabolic root subsystem. Hence, $\Psi$ is a parabolic subsystem of $\Phi$ if and only if there exists a linear subspace $H$ of $E$ such that $\Psi = \Phi \cap H$.

Posets. As usual, $\leq$ denotes both the order of $\mathbb{R}$ and the partial order of $E$ associated to $\Phi^+$: for all $x, y \in E$, $x \leq y$ if and only if $y - x \in L^+(\Phi)$. We call this last order the standard partial order. We will need only the restriction of the standard partial order to $\Phi^+$. For any $S \subseteq \Phi^+$, we denote by $\text{Min} S$ and $\text{Max} S$, with capital M, the sets of minimal and maximal elements of $S$, and by $\text{min} S$ and $\text{max} S$ its possible minimum and maximum, with respect to $\leq$. The analogous objects with respect to any other order relation $\prec$, will be distinguished by adding the subscript $\prec$. The elements in $\text{Min} S \cup \text{Max} S$ are called the extremal elements of $S$. We say that $S$ is saturated if it is saturated with respect to the standard partial order, i.e., for all $\beta_1, \beta_2 \in S$ such that $\beta_1 \leq \beta_2$, all the interval $[\beta_1, \beta_2] := \{\gamma \in \Phi \mid \beta_1 \leq \gamma \leq \beta_2\}$ is contained in $S$. Any subset $S'$ of $S$ is called an initial section of $S$ if for all $\beta \in S'$ and $\gamma \in S$, if $\gamma \leq \beta$,
then $\gamma \in S'$. The final sections are defined similarly. Then, $S'$ is an initial section of $S$ if and only if $S \prec S'$ is a final section of $S$.

For any order relation $\preceq$ on $\Phi^+$ and for all $\beta \in \Phi^+$, we denote $(\beta \preceq)$ the $\preceq$-upper cone of $\beta$, i.e.,

$$(\beta \preceq) = \{\gamma \in \Phi^+ \mid \beta \preceq \gamma\}.$$

Clearly, this is a dual order ideal, or filter, in the poset $(\Phi^+, \preceq)$.

2.2. Basic lemmas on roots.

2.2.1. General facts. We first recall some basic facts that we will use also without explicit mention. Since we are assuming $\Phi$ irreducible and reduced, the lengths of roots in $\Phi$ are at most 2 [2, Ch. VI, § 1, n. 3, 4, 5]. We denote by $\Phi_\ell$ the set of roots of maximal length (long roots), and set $\Phi_s = \Phi \setminus \Phi_\ell$ (the set of short roots). By definition, if only one length occurs, all roots are long. Results (1) to (4) below can be found in [2, Ch. VI, § 1, n. 3, 4, 5].

1. For all $\beta, \gamma \in \Phi$, if $(\beta, \gamma) < 0$ and $\beta \neq \gamma$, then $\beta + \gamma \in \Phi$. Equivalently, if $(\beta, \gamma) > 0$ and $\beta \neq \gamma$, then $-\gamma \in \Phi$.
2. For all $\beta, \gamma \in \Phi$, if $\beta \neq \gamma$ and either $\gamma \in \Phi_\ell$, or $|\beta| = |\gamma|$, then $(\beta, \gamma') \in \{0, \pm 1\}$. If $|\beta| > |\gamma|$, then $|\beta| |\beta| \in \{2, 3\}$ and $(\beta, \gamma') = (\beta, \gamma') (\beta', \gamma') \in \{0, \pm 2, \pm 3\}$.
3. For all $\beta, \gamma \in \Phi$, the set $I = \{k \in \mathbb{Z} \mid \beta + k\gamma \in \Phi\}$ is an interval of $\mathbb{Z}$.
4. For all $\alpha, \alpha' \in \Pi$, $(\alpha, \alpha') \leq 0$.

We note that in (2), since the root lengths are at most two, we have either $|\beta| |\beta| = 2$ and $(\beta, \gamma') \in \{0, \pm 2\}$ for all $\beta, \gamma \in \Phi$ such that $|\beta| > |\gamma|$, or $|\beta| |\beta| = 3$ and $(\beta, \gamma') \in \{0, \pm 3\}$ for all $\beta, \gamma \in \Phi$ such that $|\beta| > |\gamma|$.

2.2.2. Summable roots. Next proposition contains a less known result. The proof requires some basic notions and results from Lie theory. Let $\mathfrak{g}$ be a complex simple Lie algebra with root system $\Phi$ with respect to the Cartan subalgebra $\mathfrak{h}$ (see e.g. [13, §18]). Thus, $\mathfrak{g} = (\bigoplus_{\alpha \in \Phi} \mathfrak{g}_\alpha) \oplus \mathfrak{h}$, where $\mathfrak{g}_\alpha$ is the root space of $\alpha$, for all $\alpha \in \Phi$, and $(\text{Span}_C(\Phi)) = \mathfrak{h}^*$, the dual space of $\mathfrak{h}$.

We say that two roots are summable if their sum is a root. It is well known that if $\alpha$ and $\beta$ are summable roots, then $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] = \mathfrak{g}_{\alpha + \beta}$, while if $\alpha$ and $\beta$ are not summable and $\alpha \neq -\beta$, then $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] = \{0\}$.

Proposition 2.1. Let $\beta_1, \beta_2, \beta_3 \in \Phi$ be such that $\beta_1 + \beta_2 + \beta_3 \in \Phi$ and $\beta_1 \neq -\beta_3$ for all $i, j \in \{1, 2, 3\}$. Then at least two of the three sums $\beta_i + \beta_j$, with $i, j \in \{1, 2, 3\}$ and $i \neq j$, belong to $\Phi$.

Proof. For all $i \in \{1, 2, 3\}$, we have $\beta_1 + \beta_2 + \beta_3 \neq \beta_i$, otherwise, for $\{j, k\} = \{1, 2, 3\} \setminus \{i\}$, we have $\beta_1 + \beta_2 = 0$, contrary to the assumption. Moreover, for at least one $i \in \{1, 2, 3\}$ we have $(\beta_1 + \beta_2 + \beta_3, \beta_i) > 0$, since $(\beta_1 + \beta_2 + \beta_3, \beta_1 + \beta_2 + \beta_3) > 0$, hence $\beta_1 + \beta_2 + \beta_3 - \beta_i \in \Phi$. Assume for example $\beta_1 + \beta_2 \in \Phi$. Then, $[\mathfrak{g}_{\beta_1}, \mathfrak{g}_{\beta_2}, \mathfrak{g}_{\beta_3}] = [\mathfrak{g}_{\beta_1 + \beta_2 + \beta_3}] \neq \{0\}$, hence, by the Jacobi identity, at least one of $[\mathfrak{g}_{\beta_1}, \mathfrak{g}_{\beta_2}, \mathfrak{g}_{\beta_3}] = \mathfrak{g}_{\beta_1 + \beta_2 + \beta_3}$ is non zero. It follows that at least one of $\beta_1 + \beta_3$ and $\beta_2 + \beta_3$ is a root.

As we have recalled, if two roots have strictly negative scalar product, then they are summable. The reverse implication holds if $\Phi$ is simply laced, but is false in general, as we see in the following lemma, where the Cartan integers of pairs of summable roots are classified.
2.4. Ad-nilpotent and abelian ideals. Let $g$ be as in Subsection 2.2, $b$ be the standard Borel subalgebra of $g$ associated to $\Phi^+$, and $n$ its nilpotent radical, i.e., $b = \left( \bigoplus_{\alpha \in \Phi^+} g_{\alpha} \right) \oplus b$ and $n = \bigoplus_{\alpha \in \Phi^+} g_{\alpha}$.

An ad-nilpotent ideal of $b$ is a (nilpotent) ideal of $b$ contained in $n$. Being $b$-stable, such an ideal is a sum of root spaces. For any $I \subseteq \Phi^+$, the sum of root spaces $\bigoplus_{\alpha \in I} g_{\alpha}$ is an ad-nilpotent ideal of $b$ if and only if, for all $\alpha, \beta \in \Phi^+$, if $\alpha \in I$ and $\alpha \leq \beta$, then $\beta \in I$. A subset $I$ of $\Phi^+$ with this property is called an ad-nilpotent ideal of $\Phi^+$. Thus, an ad-nilpotent ideal of $\Phi^+$ is a filter in $\left( \Phi^+, \leq \right)$, i.e. a dual order ideal. It is easy to see that an abelian ideal of $b$ must be ad-nilpotent. For any $I \subseteq \Phi^+$, the subspace $\bigoplus_{\alpha \in I} g_{\alpha}$ is an abelian ideal of $b$ if and only if $I$ is an ad-nilpotent ideal of $\Phi^+$ with the further property that, for all $\alpha, \beta \in I$, $\alpha \beta \notin \Phi$. Such an $I$ is called an abelian ideal of $\Phi^+$. The abelian ideals of $\Phi^+$ are studied in several papers, both for their implications in representation theory and for their algebraic-combinatorial interest. The main representation theoretic motivations can be found in [16, 17] (see also [7]); the basic algebraic-combinatorial results can be found in [8, 9, 20, 21].

2.4. Abelian nilradicals. An ad-nilpotent ideal of $\Phi^+$ is called principal if it has a minimum, i.e. if the corresponding $b$-ideal is principal. For all $\beta \in \Phi^+$, the upper $\ll$-cone of $\beta$, $(\beta^\ll) = \{ \gamma \in \Phi^+ \mid \beta \ll \gamma \}$, is also called the principal ad-nilpotent ideal generated by $\beta$. It is clear that if $\beta \in \Phi^+$ is such that $c_{\alpha}(\beta) > m_{\alpha}^{-1}$ for some $\alpha \in \Pi$, then $(\beta^\ll)$ is abelian. In particular, this happens if $\beta$ is a simple root of multiplicity 1 in $\Phi^+$. Indeed, the following well known result holds. For completeness, we include a proof.
Proposition 2.4. Let $S \subseteq \Pi$ and $I = \Phi^+ \setminus \Phi(S)$. Then $I$ is an ad-nilpotent ideal. Moreover, $I$ is abelian if and only if either $S = \Pi$, or $S = \Pi \setminus \{\alpha\}$ for a simple root $\alpha$ such that $m_\alpha = 1$. In this case, $I$ is equal to $(\alpha^\infty)$ and is a maximal abelian ideal.

Proof. It is immediate that $I$ is an ad-nilpotent ideal. If $S = \Pi$, then $I$ is the empty root ideal, hence it is abelian. Let $S = \Pi \setminus \{\alpha\}$ with $\alpha \in \Pi$ and $m_\alpha = 1$. Then, by definition we have $I = (\alpha^\infty)$, which is abelian since $m_\alpha = 1$. We prove that $(\alpha^\infty)$ is maximal abelian. If $S = \emptyset$, i.e. $\Pi = \{\alpha\}$, then $I = \Phi^+$ and the claim is obvious. Let $S \neq \emptyset$ and let $J$ be an ad-nilpotent ideal that strictly contains $(\alpha^\infty)$. We have to prove that $J$ is not abelian. By definition, there exists $\beta \in J$ such that $\alpha \notin \text{Supp}(\beta)$. Let $\Psi_1, \ldots, \Psi_k$ be the irreducible components of $\Phi(\Pi \setminus \{\alpha\})$. Assume, for example, $\beta \in \Psi_1$. Then, if $\theta_1$ is the highest root of $\Psi_1$, we obtain $\theta_1 \in J$. Let $S_1 = \Psi_1 \cap (\Pi \setminus \{\alpha\})$. It is easily seen that, since $\Phi$ is irreducible, $\alpha$ cannot be orthogonal to the whole $S_1$. Hence, since $(\alpha, \alpha') \leq 0$ for all $\alpha' \in S_1$, there exists $\alpha' \in S_1$ such that $(\alpha', \alpha) < 0$. But $\text{Supp}(\theta_1) = S_1$, hence $(\theta_1, \alpha) \leq (\alpha', \alpha) < 0$. It follows that $\theta_1 + \alpha \in \Phi$, and hence $J$ is not abelian.

It remains to prove the “only if” part. For all $\beta \in \Phi$, let $\text{ht}_{\Pi \setminus S}(\beta) = \sum_{\alpha \in \Pi \setminus S} c_\alpha(\beta)$. We have $S = \Pi$ if and only if $\max \{\text{ht}_{\Pi \setminus S}(\beta) \mid \beta \in \Phi\} = 0$. Similarly, we have $S = \Pi \setminus \{\alpha\}$ and $m_\alpha = 1$ if and only if $\max \{\text{ht}_{\Pi \setminus S}(\beta) \mid \beta \in \Phi\} = 1$. In order to conclude the proof, we assume $\max \{\text{ht}_{\Pi \setminus S}(\beta) \mid \beta \in \Phi\} > 1$ and prove that in this case $I$ is not abelian. By definition, we have $\beta \in I$ if and only if $\text{ht}_{\Pi \setminus S}(\beta) = 0$. Let $\beta^* \in \text{Min} \{\beta \in \Phi \mid \text{ht}_{\Pi \setminus S}(\beta) > 1\}$. Since $(\beta^*, \beta^*) > 0$, there exists $\alpha \in \text{Supp}(\beta^*)$ such that $(\beta^*, \alpha) > 0$, hence $\beta^* - \alpha \in \Phi$, by 2.2.1(1). Such an $\alpha$ cannot belong to $S$, otherwise $\text{ht}_{\Pi \setminus S}(\beta^* - \alpha) = \text{ht}_{\Pi \setminus S}(\beta^*)$, contrary to minimality of $\beta^*$. It follows $\alpha \in \Pi \setminus S$, hence $\alpha \in I$. Now, $\beta^* - \alpha \in I$, too, since $\text{ht}_{\Pi \setminus S}(\beta^* - \alpha) = \text{ht}(\beta^* - 1) > 0$, hence we obtain that $I$ is not abelian since $\alpha$ and $\beta^* - \alpha$ are summable. \hfill $\square$

For each $S \subseteq \Pi$, the ideal $\bigoplus_{\alpha \in \Phi^+ \setminus \Phi(S)} g_\alpha$ is the nilradical (the largest nilpotent ideal) of the standard parabolic subalgebra associated to $S$ (see [3, Ch. VIII, § 3.4]). Hence, we call the maximal abelian ideals $(\alpha^\infty)$ with $m_\alpha = 1$, together with the empty root ideal, the abelian nilradicals.

2.5. The Faces of the Root Polytope. We recall some ideas and results from [6]. For all $\alpha \in \Pi$ and all nonempty $S \subseteq \Pi$, let

$$H_{\alpha, m_\alpha} = \{ x \in E \mid (x, \tilde{\omega}_\alpha) = m_\alpha \}, \quad F_\alpha = H_{\alpha, m_\alpha} \cap \mathcal{P}, \quad F_S = \bigcap_{\alpha \in S} F_\alpha.$$

By definition of $m_\alpha$, we have $(\beta, \tilde{\omega}_\alpha) \leq m_\alpha$ for all $\beta \in \Phi$ and, therefore, $(x, \tilde{\omega}_\alpha) \leq m_\alpha$ for all $x \in \mathcal{P}$. Hence, the affine hyperplanes $H_{\alpha, m_\alpha}$ are supporting hyperplanes of $\mathcal{P}$, and the $F_\alpha$ and $F_S$ are faces of $\mathcal{P}$. We call them the standard parabolic faces. In fact, the set of all standard parabolic faces is a set of representatives of the orbits of the action of the Weyl group $W$ on the set of proper faces of $\mathcal{P}$ [6].

For each standard parabolic face $F$, let

$$I_F = F \cap \Phi.$$

By definition, for each nonempty $S \subseteq \Pi$, $I_{F_S}$ is the set of all roots $\beta$ such that $c_\alpha(\beta) = m_\alpha$, for all $\alpha \in S$. It is easy to see that $\mathcal{P}$ is the convex hull of the long roots (see e.g. [5]), hence the long roots in $I_{F_S}$ are the vertexes of the face $F_S$.

We recall that the extended Dynkin graph of $\Phi$ is obtained from the usual Dynkin graph by extending the vertex set $\Pi$ with $-\theta$ and completing the edge set according to the scalar products and the relative lengths between $-\theta$ and the roots in $\Pi$, with the same rules used of the usual Dynkin graph. For our purposes, it is convenient to use
consider the extended Dynkin graph on the opposite vertex set, i.e., $\{\theta\} \cup -\Pi$. This does not change the edges. We call the resulting graph the opposite extended Dynkin graph.

For each $\Sigma \subseteq \Pi$, we set $\Sigma^e = \{\theta\} \cup -\Sigma$. Let $\Phi(\Sigma^e)$ be the root subsystem of $\Phi$ generated by $\Sigma^e$. For studying the face $F_S$, we need considering $\Phi(\Sigma^e)$ with $\Sigma = \Pi \setminus S$. In this case, $\Sigma \nsubseteq \Pi$, since $S$ is assumed to be nonempty. (We point out that, contrary to what is done in [6], we are not making use of the affine root system associated to $\Phi$ and all root subsystems we are defining are inside $\Phi$.)

It is well known that, if $\Sigma \nsubseteq \Pi$, then $\Sigma^e$ is a simple system for $\Phi(\Sigma^e)$ [11, Ch. II, § 5].

In general, $\Phi(\Sigma^e)$ is not irreducible. Let $\Sigma^e_\theta$ be the subset of $\Sigma^e$ defined by the condition that $\Phi(\Sigma^e_\theta)$ is the irreducible component of $\Phi(\Sigma^e)$ that contains $\theta$. Finally, let $\Sigma_\theta = \Sigma^e_\theta \setminus \{\theta\}$. We denote by $\Gamma(\Sigma^e_\theta)$ and $\Gamma(\Sigma^e_\theta)$ the subgraphs induced by $\Sigma^e$ and $\Sigma^e_\theta$ in the opposite Dynkin graph $\Phi$. Then for $\Sigma \nsubseteq \Pi$, we have that $\Gamma(\Sigma^e_\theta)$ is the Dynkin graph of $\Phi(\Sigma^e_\theta)$, and $\Gamma(\Sigma^e_\theta)$ is the connected component of $\theta$ in $\Gamma(\Sigma^e)$.

The following proposition contains the preliminary results on the standard parabolic faces that we need. We note that the proposition also precises that the face $F_S$ does not determine $S$. In fact, by parts (1) or (2), for all $S, S' \subseteq \Pi$, we have $F_S = F_{S'}$ if and only if $\Phi^+((\Pi \setminus S)_{\theta}) = \Phi^+((\Pi \setminus S')_{\theta})$, i.e., $F_S$ is uniquely determined by the irreducible component $\Phi^+((\Pi \setminus S)_{\theta})$. In particular, the standard parabolic faces, and therefore the $W$-orbits of faces, are in bijection with the proper connected subgraphs of the opposite extended Dynkin graph that contains the vertex $\theta$ [22].

**Proposition 2.5** ([6]). Let $S \subseteq \Pi$, $S \neq \emptyset$.

1. $I_{F_S} = \Phi^+((\Pi \setminus S)_{\theta}) \setminus \Phi((\Pi \setminus S)_{\theta}) = \Phi^+((\Pi \setminus S)_{\theta}) \setminus \Phi((\Pi \setminus S)_{\theta})$.
2. Let $\mu_S$ be the highest root of $\Phi((\Pi \setminus S)_{\theta})$, with respect to the simple system $(\Pi \setminus S)_{\theta}$. Then, $I_{F_S}$ is the principal abelian ideal of $\Phi^+$ generated by $\mu_S$.
3. $\dim(F_S) = |(\Pi \setminus S)_{\theta}|$.

By definition of $I_{F_S}$, part (2) says that $\mu_S$ is the unique minimal root such that $c_\alpha(\mu_S) = m_\alpha$ for all $\alpha \in S$. Both (1) and (2) implies that we have $c_\alpha(\mu_S) < m_\alpha$ if and only if $\alpha \in (\Pi \setminus S)_{\theta}$. Hence, for all $\beta \in \Phi^+$, the condition $c_\alpha(\beta) = m_\alpha$ for all $\alpha \in S$ implies $c_\alpha(\beta) = m_\alpha$ also for all $\alpha \in \Pi \setminus (\Pi \setminus S)_{\theta}$, which in general is greater than $S$.

**Definition 2.6.** We call the ideals $I_{F_S}$, for all nonempty $S \subseteq \Pi$, face ideals. The face ideals corresponding to the facets are also called facet ideals.

**Definition 2.7.** We denote by $\Phi^+((\Pi \setminus S)^c)$ the positive system of $\Phi((\Pi \setminus S)^c)$ relative to the simple system $(\Pi \setminus S)^c$. Similarly, we denote by $\Phi^+((\Pi \setminus S)^c_{\theta})$ the positive system of $\Phi((\Pi \setminus S)^c_{\theta})$ relative to the simple system $(\Pi \setminus S)^c_{\theta}$.

**Remark 2.8.** For each $S \neq \emptyset$, the positive system $\Phi^+((\Pi \setminus S)^c)$ is different from $\Phi^+((\Pi \setminus S)^c)$, which is the intersection $\Phi((\Pi \setminus S) \cap \Phi^+)$, by definition. However, we have $\Phi^+((\Pi \setminus S)^c) \setminus \Phi((\Pi \setminus S)^c) = \Phi^+((\Pi \setminus S)^c) \setminus \Phi((\Pi \setminus S)^c)$. The same considerations hold for $(\Pi \setminus S)_{\theta}$ in place of $\Pi \setminus S$. Therefore, in Proposition 2.5(1) we may replace $\Phi^+$ with $\Phi^+_{\theta}$.

By the above remark, Proposition 2.5(1) is equivalent to the following corollary.

**Corollary 2.9.** The set $I_{F_S}$ is the principal ideal generated by $\theta$ in the positive system $\Phi^+((\Pi \setminus S)_{\theta})$ of the irreducible root system $\Phi((\Pi \setminus S)_{\theta})$. 

*Algebraic Combinatorics, Vol. 1 #1 (2018)*
2.6. The order involution of face ideals. For all $w \in W$, let

$$N(w) = \{ \beta \in \Phi^+ \mid w(\beta) \leq 0 \}.$$ 

For all $\Sigma \subseteq \Pi$, let $w_{0,\Sigma}$ be the longest element in the standard parabolic subgroup of $W$ generated by $\{s_{\alpha} \mid \alpha \in \Sigma \}$. It is well known that $w_{0,\Sigma}$ is an involution and is determined by the condition $N(w_{0,\Sigma}) = \Phi^+(\Sigma)$.

**Proposition 2.10.** Let $\emptyset \neq S \subseteq \Pi$ and $w_S^* = w_{0,(\Pi-S)}$. Then, the restriction of $w_S^*$ to $I_{F_S}$ is an anti-isomorphism of the poset $(I_{F_S}, \leq)$. In particular, $w_S^*$ exchange $\theta$ and $\mu_S$.

**Proof.** We observe that, by definition, $I_{F_S} = (\theta + L(\Phi(\Pi \setminus S))) \cap \Phi$. For all $\alpha \in \Pi \setminus S$, we have $s_{\alpha}(\theta) \in \theta + L(\Phi(\Pi \setminus S))$, hence we easily obtain $s_{\alpha}(I_{F_S}) = I_{F_S}$. It follows $w_S^*(I_{F_S}) = I_{F_S}$.

It remains to prove that $w_S^*$ reverses the standard partial order on $I_{F_S}$. Let $\beta, \beta' \in I_{F_S}$ and $\beta < \beta'$. Then $\beta' - \beta \in L^+(\Phi(\Pi \setminus S))$, and since $w_S^*(\alpha) < 0$ for all $\alpha \in (\Pi \setminus S)$, $w_S^*(\beta') - w_S^*(\beta) = w_S^*(\beta' - \beta) \in -L^+(\Phi(\Pi \setminus S))$, i.e. $w_S^*(\beta') < w_S^*(\beta)$, as claimed. \(\square\)

We note that, by Proposition 2.5(1), the above proposition holds also with $w_{0,(\Pi+S)}$ in place of $w_S^*$. In particular, the restrictions of $w_{0,(\Pi+S)}$ and of $w_S^*$ on $I_{F_S}$ coincide.

**Definition 2.11.** We call $w_S^*$ the face involution of $F_S$ and the restriction of $w_S^*$ to $I_{F_S}$ the order involution of $I_{F_S}$.

3. Face ideals and abelian nilradicals

In this section we prove that the abelian nilradicals of $\Phi^+$ are facet ideals and that all face ideals are abelian nilradicals in some irreducible subsystem of $\Phi$.

By Proposition 2.5, the standard parabolic facets of $P$ are the faces of type $F_{\alpha}$ with $\alpha \in \Pi$ such that $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible. Equivalently, $F_{\alpha}$ is a facet if and only if $\alpha$ does not disconnect the extended Dynkin diagram, when removed. For type $A_n$, $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible for all $\alpha \in \Pi$. For all other root types, $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible if and only if $\alpha$ is a leaf of the extended Dynkin diagram.

In the next proposition we see that if $m_\alpha = 1$, then $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible, hence $I_{F_{\alpha}}$ is a facet ideal. We note that in this case $I_{F_{\alpha}} = (\alpha^S)$.

**Proposition 3.1.** Each nonempty abelian nilradical of $\Phi^+$ is a facet ideal.

**Proof.** It is well known that if $\alpha$ is any simple root such that $m_\alpha = 1$, then the subgraph of the extended Dynkin graph obtained by removing $\alpha$ is isomorphic to the (ordinary) Dynkin graph of $\Phi$ [15]. In particular, $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible, hence $(\Pi \setminus \{\alpha\})^0 = (\Pi \setminus \{\alpha\})$ and $(\Pi \setminus \{\alpha\})_0 = \Pi \setminus \{\alpha\}$. By Proposition 2.5(3), we have $\dim(F_{\alpha}) = |\Pi \setminus \{\alpha\}| = n - 1$, i.e., $F_{\alpha}$ is a facet. \(\square\)

If $m_\alpha = 1$, then $\alpha$ is the minimum of $I_{F_{\alpha}}$, hence, the order involution $w_{0,\Pi \setminus \{\alpha\}}$ maps $\alpha$ onto $\theta$. Since it also maps $\Pi \setminus \{\alpha\}$ onto $-(\Pi \setminus \{\alpha\})$, it maps $\Pi$ onto the nodes of the opposite extended Dynkin graph minus the node $-\alpha$. Hence, the fact that $\Phi((\Pi \setminus \{\alpha\})^o)$ is isomorphic to $\Phi$ for all $\alpha$ with $m_\alpha = 1$, is a consequence of Proposition 2.10.

By a direct check, we can see that, for the root types $A_n, C_n, D_n,$ and $E_6$, we have that $\Phi((\Pi \setminus \{\alpha\})^o)$ is irreducible if and only if $m_\alpha = 1$. For the other root types, there exists at least a leaf $\alpha \in \Pi$ of the extended Dynkin diagram such that $m_\alpha > 1$. Then, $F_{\alpha}$ is a facet, but $I_{F_{\alpha}}$ is not an abelian nilradical in $\Phi$. Thus, the converse of Proposition 3.1 is not true. However, the following result holds.
Each face ideal in $\Phi^+$ is an abelian nilradical of some irreducible root subsystem of $\Phi$.

Proof. By Corollary 2.9, any face ideal $I_{F_{\mathcal{S}}}$ ($\emptyset \neq \mathcal{S} \subseteq \Pi$) is the principal ideal generated by $\theta$ in the positive system $\Phi^+((\Pi \setminus \mathcal{S})_{\emptyset})$.

By Definition 2.7, the simple system of $\Phi^+((\Pi \setminus \mathcal{S})_{\emptyset})$ is $((\Pi \setminus \mathcal{S})_{\emptyset})^\circ$, and $((\Pi \setminus \mathcal{S})_{\emptyset})^\circ = \{\theta\} \cup (\Pi \setminus \mathcal{S})_{\emptyset}$, where $(\Pi \setminus \mathcal{S})_{\emptyset}$ is a certain subset of $-(\Pi \setminus \mathcal{S})$. Hence, for all $\beta \in \Phi^+((\Pi \setminus \mathcal{S})_{\emptyset})^\circ$, we have $\beta = c_\theta \theta - \sum_{\alpha \in \Pi \setminus \mathcal{S}} c_\alpha \alpha$, for some nonnegative $c_\theta, c_\alpha$. This implies that, for all $\alpha \in S$, $c_\alpha(\beta) = c_\alpha m_\alpha$ and, hence, $c_\alpha \leq 1$. In other words, the multiplicity of $\theta$, as a simple root in the positive system $\Phi^+((\Pi \setminus \mathcal{S})^\circ)$, is 1. Hence, the principal ideal generated by $\theta$ in $\Phi^+((\Pi \setminus \mathcal{S})^\circ)$ is an abelian nilradical. □

Remark 3.3. Let $\alpha \in \Pi$ be such that $F_\alpha$ is a facet. By Proposition 2.5, $I_{F_\alpha}$ is also equal to $\left(\mu_{\{\alpha\}}^\circ\right)$, where $\mu_{\{\alpha\}}$ is the unique root in $\Phi$ such that $c_\alpha(\mu_{\{\alpha\}}) = m_\alpha$ and $c_\alpha'(\mu_{\{\alpha\}}) < m_\alpha$ for all $\alpha' \in \Pi \setminus \{\alpha\}$. By Proposition 2.10, the face involution $w_{\{\alpha\}}$ maps $(\Pi \setminus \{\alpha\})^\circ$ onto $[\mu_{\{\alpha\}}] \cup (\Pi \setminus \{\alpha\})$, therefore, this last set is a simple system for $\Phi((\Pi \setminus \{\alpha\})^\circ)$. In fact, $[\mu_{\{\alpha\}}] \cup (\Pi \setminus \{\alpha\})$ is the simple system of the positive system $\Phi^+((\Pi \setminus \{\alpha\})^\circ)$.

Since $w_{\{\alpha\}}(\beta) = \mu_{\{\alpha\}}$, by the proof of Proposition 3.2 we obtain that the multiplicity of $\mu_{\{\alpha\}}$, as a simple root in $\Phi^+((\Pi \setminus \{\alpha\})^\circ)$, is 1. Hence, $I_{F_\alpha}$ is the abelian nilradical generated by $\mu_{\{\alpha\}}$ in the positive system $\Phi^+((\Pi \setminus \{\alpha\})^\circ)$.

The definition of ad-nilpotent and abelian ideals makes sense also in the reducible case. Let $\Psi$ be any finite crystallographic root system, $\Psi_1, \ldots, \Psi_k$ be its irreducible components, $\Psi^+_i$ a positive system for $\Psi_i$, for $i = 1, \ldots, k$, and $\Psi^+ = \Psi^+_1 \cup \cdots \cup \Psi^+_k$. Then, by definition, $I$ is an ad-nilpotent, or abelian, ideal of $\Psi^+$ if and only if $I \cap \Psi^+_i$ is an ad-nilpotent, or abelian, ideal of $\Psi^+_i$ for all $i \in \{1, \ldots, k\}$. Moreover, $I$ is an abelian nilradical of $\Psi^+$ if and only if $I \cap \Psi^+_i$ is an abelian nilradical of $\Psi^+_i$ for all $i \in \{1, \ldots, k\}$. This means that $I \cap \Psi^+_i$ is either empty or a principal ideal generated by a simple root with multiplicity 1.

Proposition 3.4. Let $I$ be an abelian nilradical of $\Phi^+$ and $\Psi$ a root subsystem of $\Phi$. Then $I \cap \Psi$ is an abelian nilradical of $\Psi^+$.

Proof. Let $\Psi_1, \ldots, \Psi_k$, for $i = 1, \ldots, k$, be the irreducible components of $\Psi$. We have to prove that $I \cap \Psi_i$ is an abelian nilradical of $\Psi^+_i$ for $i = 1, \ldots, k$, hence we may directly assume that $\Psi$ is irreducible.

Let $I = \{\alpha_i^\circ\}$, with $\alpha_i \in \Pi$ and $m_\alpha = 1$. Let $\Pi_\Psi$ be the simple system of $\Psi^+$, and $\theta_\Psi = \sum_{\beta \in \Pi_\Psi} m_\beta' \beta$ be the highest root in $\Psi$.

If $I \cap \Psi = \emptyset$ we are done.

If there exists some $\beta$ in $I \cap \Psi$, then $\beta \leq \theta_\Psi$ and hence $\theta_\Psi \in I$, i.e., $c_\alpha(\theta_\Psi) = 1$. Let $\Pi_\Psi(\alpha) = I \cap \Pi_\Psi$. By definition, we have $c_\alpha(\beta) = 1$ for all $\beta \in \Pi_\Psi(\alpha)$. Moreover, since $\Pi_\Psi \subseteq \Phi^+$, we have $c_\alpha(\beta) = 0$ for all $\beta \in \Pi_\Psi \setminus I$. Hence, $1 = c_\alpha(\theta_\Psi) = \sum_{\beta \in \Pi_\Psi(\alpha)} m_\beta'$. Since all coefficients $m_\beta'$ are strictly positive, we obtain that there exists a unique root $\beta^*$ such that $\Pi_\Psi(\alpha) = \{\beta^*\}$. Moreover, we have $m_{\beta^*}' = 1$, i.e., by definition, $\beta^*$ has multiplicity 1 as a simple root of $\Psi$. Finally, for all $\gamma \in \Psi$, let $\gamma = \sum_{\beta \in \Pi_\Psi} c_{\beta}(\gamma) \beta$ be the decomposition of $\gamma$ with respect to the basis $\Pi_\Psi$. Then, $c_{\alpha}(\gamma) = c_{\beta^*}(\gamma)$, hence, $\gamma \in I \cap \Psi$ if and only if $c_{\beta^*}(\gamma) = 1$. It follows that $I \cap \Psi$ is the principal ideal generated by $\beta^*$ in $\Psi^+$, and hence it is an abelian nilradical of $\Psi^+$. □

From the above proof, we obtain also the following refinement of Proposition 3.4.

Algebraic Combinatorics, Vol. 1 #1 (2018)
Proof. (1) We prove that \( x, \beta \) are roots. If \( x \neq 0 \) and only if \( I \cap \Psi \neq \emptyset \); (2) if \( I \cap \Psi \neq \emptyset \), then \( I \cap \Psi \) consists of a single element; (3) if \( I \cap \Psi = \{ \beta^* \} \), then \( \beta^* \) as a simple root of \( \Psi^+ \), has multiplicity 1, and \( I \cap \Psi \) is the abelian nilradical generated by \( \beta^* \) in \( \Psi^+ \), i.e. \( I \cap \Psi = \Psi^+ \setminus \Phi(I \cap \Psi \setminus \{ \beta^* \}) \).

4. Crossing pairs

In this section we analyze the properties of crossing pairs contained in abelian ideals. In the simply laced case, many of the results that we are proving could be proved in a very simpler way.

Definition 4.1. Let \( \beta_i, \gamma_i \in \Phi, \ i = 1, 2 \), with \( \beta_i \neq \gamma_j \) for all \( i, j \in \{1, 2\} \). We say that \( \{\beta_1, \beta_2\} \) and \( \{\gamma_1, \gamma_2\} \) are crossing pairs if \( \beta_1 + \beta_2 = \gamma_1 + \gamma_2 \). In this case we call the equality \( \beta_1 + \beta_2 = \gamma_1 + \gamma_2 \) a crossing relation. We do not assume that \( \beta_1 \neq \beta_2 \) and \( \gamma_1 \neq \gamma_2 \), hence (at most) one of the pairs \( \{\beta_1, \beta_2\} \) and \( \{\gamma_1, \gamma_2\} \) may be a multiset of a single root with multiplicity 2.

Lemma 4.2. Let \( I \) be an abelian ideal in \( \Phi^+ \), and \( \beta, \gamma \in I \).

1. If \( \beta \in \Phi_+ \), \( x \in \Phi \), and \( \beta + x \in I \), then \( x \in \Phi_+ \).
2. If \( \beta - \gamma \in \Phi \), then \( (\beta, \gamma) > 0 \).

Proof. (1) We prove that \( |\beta| \geq |x| \), which yields the claim. By contradiction, let \( |\beta| < |x| \). Then, by Lemma 2.2(3), \( (x, \beta') \in \{ -2, -3 \} \). It follows \( s_{ij}(x) = x - (x, \beta') \beta \geq x + 2\beta \), hence \( x + 2\beta \in \Phi \), which is contrary to the fact that \( I \) is abelian, since \( x + 2\beta = \beta + (x + \beta) \) and \( \beta, x + \beta \in I \).

(2) By Proposition 2.3(1), applied to the summable roots \( \beta, -\gamma \), we have \( (\beta, -\gamma) \geq 0 \) if and only if \( \beta, -\gamma \in \Phi_+ \) and \( \beta - \gamma \in \Phi_+ \). By part (1) this cannot happen. Indeed, since \( \gamma + (\beta - \gamma) \in I \), if \( \gamma \in \Phi_+ \), we must have \( \beta - \gamma \in \Phi_+ \). Therefore, \( (\beta, -\gamma) < 0 \), which gives the claim.

Proposition 4.3. Let \( I \) be an abelian ideal in \( \Phi^+ \) and \( \{\beta_1, \beta_2\}, \{\gamma_1, \gamma_2\} \) be crossing pairs contained in \( I \) such that \( \beta_1 \neq \beta_2 \). Then:

1. for all \( i, j \in \{1, 2\} \) we have \( (\beta_i, \gamma_j) > 0 \), in particular \( \beta_i - \gamma_j \) is a root;
2. either \( \{\beta_1, \beta_2\} \), or \( \{\gamma_1, \gamma_2\} \) is the pair of the minimum and maximum of \( \{\beta_i, \gamma_i \mid i = 1, 2\} \);
3. \( (\beta_1, \beta_2) = 0 \) unless both of \( \beta_1, \beta_2 \) are short and \( \gamma_1, \gamma_2 \) have different lengths.

Proof. (1) If \( \{i, i'\} = \{1, 2\} \), we have \( \beta_1 + \beta_2 - \gamma_i = \gamma_j' \in \Phi \). Moreover, since \( I \) is abelian, \( \beta_1 + \beta_2 \not\in \Phi \). By Proposition 2.1, applied to the summable triad \( \beta_1, \beta_2, -\gamma_i \), we obtain \( \beta_j - \gamma_i \in \Phi \) for \( j \in \{1, 2\} \). By Lemma 4.2(2), it follows \( (\beta_j, \gamma_i) > 0 \) for \( i, j \in \{1, 2\} \).

(2) We set \( x = \gamma_1 - \beta_1 = \beta_2 - \gamma_2 \) and \( y = \gamma_2 - \beta_1 = \beta_2 - \gamma_1 \). By part (1), \( x \) and \( y \) are roots. If \( x \) and \( y \) are both positive or both negative, we directly obtain that \( \{\beta_1, \beta_2\} \) is the set of the minimum and maximum of \( \{\beta_i, \gamma_i \mid i = 1, 2\} \). Similarly, if one of \( x, y \) is positive and the other is negative, \( \{\gamma_1, \gamma_2\} \) is the set of the minimum and maximum \( \{\beta_i, \gamma_i \mid i = 1, 2\} \). (In the picture below we illustrate the Hasse diagram of the quadruple \( \{\beta_1, \beta_2, \gamma_1, \gamma_2\} \) in the cases \( x, y > 0 \) and \( x > 0, y < 0 \).)
(3) We keep the notation of part (2). First, we assume that at least one of $\beta_1, \beta_2$ is long and prove that then $(\beta_1, \beta_2) = 0$. Let $\beta_1$ be long. Then, by Proposition 2.3 (2), applied to the two pairs of summable roots $\beta_1, -\gamma_2$ and $\beta_1, x$, we have $-(\beta_1, \gamma_2) = (\beta_1, x) = -1$. Hence, $(\beta_1', \beta_2) = (\beta_1', \gamma_2 + x) = 0$, which yields the claim. The case $\beta_2$ long is similar.

Now, we assume $\beta_1, \beta_2 \in \Phi_s$ and $(\beta_1, \beta_2) \neq 0$, and we prove that $|\gamma_1| \neq |\gamma_2|$. Since $I$ is abelian, $\beta_1$ and $\beta_2$ are not summable, hence cannot have negative scalar product. Therefore $(\beta_1, \beta_2) > 0$, and since $|\beta_1| = |\beta_2|$, by 2.2.1(2) we have $(\beta_1', \beta_2) = 1$. By definition, we have $\beta_2 = \gamma_1 + y = \beta_1 + x + y$, hence $1 = (\beta_1', \beta_2) = (\beta_1', \beta_1) + (\beta_1', x) + (\beta_1', y) = 2 + (\beta_1', x) + (\beta_1', y)$. It follows $(\beta_1', x) + (\beta_1', y) = -1$. But, by Lemma 4.2(1), $x$ and $y$ are short, hence $(\beta_1', x), (\beta_1', y) \in \{0, \pm 1\}$ (by 2.2.1(2), again). Therefore $\{x, y\} = \{0, -1\}$. We may assume $(\beta_1', x) = 0$ and $(\beta_1', y) = -1$, without loss of generality. Then, by Proposition 2.3(1), applied to the two summable pairs of short roots $\beta_1, x$ and $\beta_1, y$, we obtain $|\beta_1| = |x| < |\beta_1 + x| = |\gamma_1|$, and $|\beta_1| = |y| \geq |\beta_1 + y| = |\gamma_2|$. Hence, $\gamma_1$ is long and $\gamma_2$ is short. □

**Note 4.4.** We write $\beta_1 \leq \{\gamma_1, \gamma_2\} < \beta_2$ for $\beta_1 \leq \gamma_i < \beta_2$ for both $i \in \{1, 2\}$.

Let $\{\beta_1, \beta_2\}$ and $\{\gamma_1, \gamma_2\}$ be crossing pairs. Up to exchange $\beta_1$ and $\beta_2$, we may assume $\beta_2 \leq \beta_1$. Similarly, without loss of generality, we may assume $\gamma_2 \leq \gamma_1$. Then, by Proposition 4.3(2), either $\beta_1 \leq \{\gamma_1, \gamma_2\} < \beta_2$, or $\gamma_1 \leq \{\beta_1, \beta_2\} < \gamma_2$.

**Definition 4.5.** We define the relations $\leq$ and $\sim$ on $\Phi^+$ as follows:

$\beta_1 \preceq \beta_2$ if and only if there exists $\gamma_1, \gamma_2 \in \Phi^+$ such that $\{\beta_1, \beta_2\}$ and $\{\gamma_1, \gamma_2\}$ are crossing pairs with $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$;

$\beta_1 \sim \beta_2$ if and only if either $\beta_1 \preceq \beta_2$ or $\beta_2 \preceq \beta_1$.

If $\{\beta_1, \beta_2\}$ and $\{\gamma_1, \gamma_2\}$ are crossing pairs with $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$, we also say that $\{\gamma_1, \gamma_2\}$ is a middle pair between $\beta_1$ and $\beta_2$ and that $\{\beta_1, \beta_2\}$ is a raising pair through $\gamma_1$ and $\gamma_2$.

In the next corollary we study the order relations among different raising pairs through a common middle pair and different middle pairs between a common raising pair.

**Corollary 4.6.** Let $I$ be an abelian ideal, $\{\beta_1, \beta_2\}$ and $\{\gamma_1, \gamma_2\}$ be crossing pairs in $I$ with $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$.

1. If $\{\beta_1', \beta_2'\}$ is any other raising pair through $\{\gamma_1, \gamma_2\}$, with $\beta_1' < \beta_2'$, then either $\beta_1 < \beta_1' < \beta_2 < \beta_2'$ or $\beta_1' < \beta_1 < \beta_2 < \beta_2'$. Moreover, $\beta_1 - \beta_1' \in \Phi$ for both $i = 1, 2$.

2. If $\{\gamma_1', \gamma_2'\}$ is any other middle pair between $\{\beta_1, \beta_2\}$, then $\gamma_i - \gamma_i' \in \Phi$ for all $i, j \in \{1, 2\}$. Moreover, one of the following four cases occur: $\gamma_1' < \{\gamma_1, \gamma_2\} < \gamma_2'$, $\gamma_1 < \{\gamma_1', \gamma_2\} < \gamma_2$ (with $\{i, j\} = \{1, 2\}$). In particular, there exists at most one incomparable middle pair between $\beta_1$ and $\beta_2$.

**Proof.** Under the assumption of (1), we have $\beta_1' + \beta_2' = \gamma_1 + \gamma_2 = \beta_1 + \beta_2$, hence $\{\beta_1', \beta_2'\}$ and $\{\beta_1, \beta_2\}$ are crossing pairs. Similarly, under the assumption of (2), $\{\gamma_1', \gamma_2\}$ and
\{\gamma_1, \gamma_2\} are crossing pairs. Hence, the claim follows directly from Proposition 4.3(2). 

In the next lemma, we see that the possible lengths of roots and root differences in a crossing pair are very limited.

**Lemma 4.7.** Let \( I \) be an abelian ideal in \( \Phi^+ \), \( \{\beta_1, \beta_2\} \), \( \{\gamma_1, \gamma_2\} \) be crossing pairs contained in \( I \), \( \beta_1 < \{\gamma_1, \gamma_2\} < \beta_2 \), \( x = \beta_2 - \gamma_2 = \gamma_1 - \beta_1 \), and \( y = \beta_2 - \gamma_1 = \gamma_2 - \beta_1 \).

1. If either one of \( x \), \( y \) is long, then \( x, y, \beta_1, \beta_2, \gamma_1, \gamma_2 \) are all long.
2. If any one of \( x, y, \beta_1, \beta_2, \gamma_1, \gamma_2 \) is short, then \( x \) and \( y \) are short and at most one of \( \beta_1, \beta_2, \gamma_1, \gamma_2 \) is long, except when \( \gamma_1 = \gamma_2 \), in which case \( \gamma_1 \) is short and \( \beta_1, \beta_2 \) are long.

**Proof.** We first prove that:

(a) if any one of \( \beta_1, \beta_2, \gamma_1, \gamma_2 \) is short, then \( x \) and \( y \) are short.

We provide the details for the case \( \gamma_2 \in \Phi_s \). The other cases are similar. We have \( \gamma_2 + x = \beta_2 \), in particular \( \gamma_2 + x \in I \), hence by Lemma 2.4(1), we obtain \( x \in \Phi_s \).

Similarly, since \( \gamma_2 + (-y) = \beta_1 \in I \) we obtain \(-y \in \Phi_s \), hence the claim.

Now we prove that:

(b) \( x \) and \( y \) are either both short, or both long.

It suffices to prove that if either one of \( x \), \( y \) is short, then the other one is short, too. Assume, for example, \( x \in \Phi_s \). By (a), it suffices to prove that at least one among \( \beta_1, \gamma_i \) \((i = 1, 2)\), is short. If \( \beta_1 \in \Phi_s \), we are done. Then, let \( \beta_1 \in \Phi_r \). By Lemma 4.2(3), the sum of two roots of different lengths is always short, hence \( \gamma_1 = \beta_1 + x \) is short and we are done. The case \( y \in \Phi_r \) is similar, hence (b) is proved.

Now we conclude the proof of part (1). If either one of \( x \), \( y \) is long, then, by (a), \( \beta_1 \) and \( \gamma_1 \) are long, for \( i = 1, 2 \). Moreover, by (b), both of \( x \) and \( y \) are long.

It remains to conclude the proof of part (2). So, we assume \( \{x, y, \beta_1, \beta_2, \gamma_1, \gamma_2\} \not\subset \Phi_r \). Then, by part (1), \( x, y \in \Phi_s \). We distinguish the two cases \( \gamma_1 \neq \gamma_2 \) and \( \gamma_1 = \gamma_2 \).

Let \( \gamma_1 \neq \gamma_2 \). We have to prove that if any root in \( \{\beta_1, \beta_2, \gamma_1, \gamma_2\} \) is long, then the three remaining roots are short.

Let \( \beta_1 \in \Phi_r \). By Lemma 2.2(3) the sum of a long and a short root is short, hence we obtain \( \gamma_1, \gamma_2 \in \Phi_s \), since \( \gamma_1 = \beta_1 + x \) and \( \gamma_2 = \beta_1 + y \). Then, we have \( \gamma_1 \not\in \Phi_s \), while \( \gamma_1 + (-x) = \beta_1 \in \Phi_f \). By Proposition 3.3(1), this implies \( \gamma_1 \not\in \Phi_f \).

If \( \beta_2 \in \Phi_r \), arguing in a similar way, we obtain \( \gamma_1, \gamma_2 \in \Phi_s \). Moreover, \( \gamma_1, y \not\in \Phi_r \).

Now, if both \( \beta_1, \beta_2 \in \Phi_r \), we deduce \( \gamma_1 \not\in \Phi_s \). Moreover, \( \gamma_1, y \not\in \Phi_r \).

Since \( |\gamma_1| = |\gamma_2| \), by 2.2.1(2) this implies \( \gamma_1 = \gamma_2 \), contrary to the assumption.

By a similar argument, taking into account that \( \beta_1 \neq \beta_2 \), we obtain that if one of \( \gamma_1, \gamma_2 \) is long, the three remaining roots in the crossing pairs are short, as claimed.

Now, let \( \gamma_1 = \gamma_2 \). We have to prove that \( \gamma_1 \in \Phi_s \) and \( \{\beta_1, \beta_2\} \subset \Phi_r \). Indeed, we have \( \beta_1 + \beta_2 = 2\gamma_1 \), hence \( \langle \beta_1, \beta_2, \gamma_1 \rangle = 4 \). By 2.2.1(2), it follows that either \( \langle \beta_1, \gamma_1 \rangle = \langle \beta_2, \gamma_1 \rangle = 2 \), or \( \langle \beta_1, \gamma_1 \rangle = 1 \) and \( \langle \beta_2, \gamma_1 \rangle = 3 \). In the first case we obtain \( \gamma_1 \in \Phi_s \) and \( \beta_1, \beta_2 \in \Phi_r \), as claimed. The latter case cannot happen, otherwise we obtain \( s_\gamma(-\beta_2) = -\beta_2 + 3\gamma_1 \in \Phi \), and \( -\beta_2 + 3\gamma_1 = (-\beta_2 + 2\gamma_1) + \gamma_1 = \beta_1 + \gamma_1 \), contrary to abelianity of \( I \).

\( \square \)

In the next proposition, we prove that, for any pair of comparable roots \( \beta_1 \) and \( \beta_2 \) in an abelian ideal \( I \), if \( \beta_1 - \beta_2 \) is not a root, then \( \beta_1 \sim \beta_2 \). Moreover, we analyze when the reverse implication holds. We need the following well known result.

**Lemma 4.8** ([2, Ch. VI, § 1.9, Proposition 19]). Let \( \gamma_1, \ldots, \gamma_m \in \Phi^+ \). If \( \gamma_1 + \cdots + \gamma_m \in \Phi^+ \), there exists a permutation \( (\gamma'_1, \ldots, \gamma'_m) \) of \( (\gamma_1, \ldots, \gamma_m) \) such that \( \gamma'_1 + \cdots + \gamma'_h \in \Phi \) for all \( h \in \{1, \ldots, m\} \).
Proposition 4.9. Let I be an abelian ideal in $\Phi^+$ and $\beta_1, \beta_2 \in I$.

1. If $\beta_1 < \beta_2$ and $\beta_2 - \beta_1 \notin \Phi$, then $\beta_1 \leq \beta_2$.
2. If $\beta_1 \leq \beta_2$, then $\{\beta_1, \beta_2\} \subseteq \Phi_\ell$ and there exists a middle pair $\{\gamma_1, \gamma_2\}$ between $\beta_1, \beta_2$ such that $\gamma_1 \in \Phi_\ell$ and $\gamma_2 \in \Phi_f$, then $\beta_2 - \beta_1 \notin \Phi_\ell$.
3. If $\beta_1 \leq \beta_2$, then $\beta_2 - \beta_1 \notin \Phi$ if and only if either one of the following conditions is satisfied:
   a. at least one of $\beta_1, \beta_2$ is long,
   b. $\{\beta_1, \beta_2\} \subseteq \Phi_\ell$ and there exists a middle pair $\{\gamma_1, \gamma_2\} \subseteq \Phi_\ell$ between $\beta_1, \beta_2$.

Proof. (1) Let $\beta_1 < \beta_2$ and $\beta_2 - \beta_1 \notin \Phi$. By definition, $\beta_2 - \beta_1$ is a sum of positive roots. Let

$$k = \min\{h \in \mathbb{N} \mid \exists n_1, \ldots, n_k \in \Phi^+ \text{ such that } \beta_2 - \beta_1 = n_1 + \cdots + n_k\},$$

and $n_1, \ldots, n_k \in \Phi^+$ be such that $\beta_2 = \beta_1 + n_1 + \cdots + n_k$. By assumption, $k \geq 2$. Moreover, by minimality of $k$, no partial sum $\sum_{j=1}^h n_j$, with $1 \leq i_j \leq k$ and $h > 1$ is a root.

By Lemma 4.8, we may find a permutation $(\gamma'_{n_1}, \ldots, \gamma'_{n_k})$ of the sequence $(\beta_1, n_1, \ldots, n_k)$ such that all partial sums $\gamma'_1 + \cdots + \gamma'_j$ are roots. By the above discussion, $\beta_1$ must be either $\gamma'_1$ or $\gamma'_{1'}$. In both cases, we easily obtain that there exists a permutation $(n'_1, \ldots, n'_k)$ of $(n_1, \ldots, n_k)$ such that $\beta_1 + \sum_{1 \leq j \leq k} n'_j \in \Phi$ for all $h \in \{0, \ldots, k\}$.

Now, we prove that also $\beta_2 - n'_i = \beta_1 + \sum_{2 \leq j \leq k} n'_j \in \Phi$. This yields the crossing relation $\beta_1 + \beta_2 = (\beta_1 + n'_1) + (\beta_2 - n'_1)$, which concludes the proof of (1).

Let $\gamma_h = \beta_1 + \sum_{1 \leq j \leq h} n'_j$, so that $\gamma_h = \beta_2$. We prove, by induction on $h$, that $\gamma_h - n_h \notin \Phi$ for all $h \in \{1, \ldots, k\}$. For $h = 1$, the claim is clear, since $\gamma_1 = \beta_1 + n'_1$, by definition. Assume $1 \leq h < k$ and $\gamma_h - n'_h \notin \Phi$. We have

$$\gamma_{h+1} = \gamma_h + n'_{h+1} = (\gamma_h - n'_h) + n'_h + n'_{h+1}.$$

By our assumption, $n'_h + n'_{h+1} \notin \Phi$, hence, by Proposition 2.1, applied to the summable triad $(\gamma_h - n'_h, n'_h, n'_{h+1})$, we obtain that $(\gamma_h - n'_h) + n'_{h+1}$ is a root (and also $(\gamma_h - n'_h) + n'_h$ is a root). Since $(\gamma_h - n'_h) + n'_{h+1} = \gamma_{h+1} - n'_h$, we get the claim.

(2) Let $\beta_1 + \beta_2 = \gamma_1 + \gamma_2$, $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$, $\beta_1, \beta_2, \gamma_1 \in \Phi_\ell$, and $\gamma_2 \in \Phi_f$. We have to prove that $\beta_2 - \beta_1 \notin \Phi_\ell$. First, we see that the condition $(\beta_2, \beta'_1) > 0$ implies the claim. Indeed, by 2.2.1(1) if $(\beta_2, \beta'_1) > 0$, then $\beta_2 - \beta_1 \notin \Phi$. Moreover, $\beta_2 - \beta_1 \notin \Phi_\ell$, otherwise, by Proposition 2.3 (1), we should have $(\beta_2, -\beta'_1) > 0$.

Thus, we prove that $(\beta_2, \beta'_1) > 0$. Let $x = \beta_2 - \gamma_2 = \gamma_1 - \beta_1$. We recall that $x$ is short, by Lemma 4.7 (1). Then, $(\beta_2, \beta'_1) = (\gamma_2, \beta'_2) + (x, \beta'_1)$, and our assumptions on lengths imply $(x, \beta'_1) \in \{0, \pm 1\}$ and $(\gamma_2, \beta'_2) \in \{0, \pm 2, \pm 3\}$, by 2.2.1(2). Moreover, $(\gamma_2, \beta'_2)$ is positive, by Proposition 4.3(1), hence, $(\gamma_2, \beta'_2) \geq 2$ and $(\beta_2, \beta'_1) \geq 2-1 = 1$, as claimed.

(3) For proving the “if” part, it suffices to prove that if neither (a), nor (b) hold, then the assumption of (2) holds. First, we assume that (a) does not hold, i.e., $\beta_1, \beta_2 \in \Phi_\ell$. Then, by Lemma 4.7 (2), for all middle pairs $\{\gamma_1, \gamma_2\}$ between $\beta_1, \beta_2$, at most one of $\gamma_1, \gamma_2$ is long. It follows that either (b) holds, or all middle pairs $\{\gamma_1, \gamma_2\}$ satisfies the assumption in (2).

It remains to prove the “only if” part. Let $\gamma_1, \gamma_2 \in \Phi$ be such that $\beta_1 + \beta_2 = \gamma_1 + \gamma_2$ and $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$.

(a) Assume $\beta_2 \notin \Phi_\ell$ and, as before, let $x = \gamma_1 - \beta_1 = \beta_2 - \gamma_2$ and $y = \gamma_2 - \beta_1 = \beta_2 - \gamma_1$. Since the pairs of $\beta_2, -x$ and $\beta_2, -y$ are summable, by Proposition 2.3(2) we
obtain \((x, β_2') = (y, β_2') = 1\). Hence,
\[(*) \quad 2 = (β_2, β_2') = (β_1 + x + y, β_2') = (β_1, β_2') + 2.\]
It follows \((β_1, β_2') = 0\) and, by Proposition 2.3(2), \(β_2 - β_1 ∈ Φ\). If \(β_1 ∈ Φ_ε\), we may argue in a similar way and find again \(β_2 - β_1 ∈ Φ\).

(b) Let \(β_1, β_2 ∈ Φ_s\). By Proposition 4.7 (1), we have \(x, y ∈ Φ_s\), hence, by applying Lemma 2.2 (1) to the summable pairs \(β_2, -x\) and \(β_2, -y\), we obtain that equalities \((*)\) still hold. Hence, also in this case we have \(β_2 - β_1 ∈ Φ\).

The following corollary follows directly from parts (1) and (3) of Proposition 4.9.

**Corollary 4.10.** Let \(I\) be an abelian ideal in \(Φ^+\), and \(β_1, β_2 ∈ I\). If either one of \(β_1, β_2\) is long, then \(β_1 ∼ β_2\) if and only if \(β_1 < β_2\) and \(β_2 - β_1 ∈ Φ\).

If we combine parts (2) and (3) of Proposition 4.9, we obtain that the root lengths of all middle pairs between two fixed short roots \(β_1, β_2\) are uniquely determined by \(β_1, β_2\).

**Corollary 4.11.** Let \(I\) be an abelian ideal in \(Φ^+\), \(β_1, β_2 ∈ I ∩ Φ_s\), and \(β_1 ∼ β_2\). Then either \(γ_1, γ_2 ∈ Φ_s\) for all middle pairs \(\{γ_1, γ_2\}\) between \(β_1, β_2\), or \(γ_1\) and \(γ_2\) have different lengths for all middle pairs \(\{γ_1, γ_2\}\) between \(β_1, β_2\).

**Proof.** Let \(\{γ_1, γ_2\}\) and \(\{γ_1', γ_2'\}\) be middle pairs between \(β_1, β_2\). By Proposition 4.7(2), at least one of \(γ_1, γ_2\) and at least one of \(γ_1', γ_2'\) are short. If \(\{γ_1, γ_2\} ∉ Φ_s\), then, by part (2) of Proposition 4.9, we have \(β_2 - β_1 ∈ Φ_s\), while if \(\{γ_1', γ_2'\} ∉ Φ_s\), then, by part (3) we have \(β_2 - β_1 ∉ Φ\). Hence the two possibilities mutually exclude each other. \(□\)

**Definition 4.12.** For any \(S ⊆ Φ^+\), we say that \(S\) is reduced if, for all \(β, β' ∈ S, β ≠ β'\),

for all \(β ∈ Φ^+\) we set
\[\text{Red}(β) = \{β' ∈ Φ^+ | β ≠ β' \text{ and } β ∉ β'\}.\]

**Remark 4.13.** By Proposition 4.9(1) and Lemma 4.2(2), if \(I\) is an abelian ideal, \(β ∈ I\), and \(I(β^+) = \{γ ∈ I | γ\) is comparable with \(β\}\), then
\[(1) \quad \text{Red}(β) ∩ I(β^+) ⊆ \{γ ∈ I | γ - β ∈ Φ^+\} = \{γ ∈ I \setminus \{β\} | (γ, β) > 0\}.\]
If \(β ∈ Φ_ε\), in particular in the simply laced case, the inclusion is an equality, by Corollary 4.10. Moreover, if \(β ∈ Φ_ε\), we have \((γ, β^+) ∈ \{0, ±1\}\) for all \(γ ∈ Φ \setminus \{β\}\), hence
\[(2) \quad \text{Red}(β) ∩ I(β^+) = \{γ ∈ I | (γ, β^+) = 1\}.\]
In general, the inclusion in (1) is proper. As an example, for \(Φ\) of type \(C_n\), if we number the simple roots as in [2] and take \(I = (α_n^+)\), \(β_1 = α_n + α_{n−1}, β_2 = α_n + 2α_{n−1} + α_{n−2}, γ_1 = α_n + α_{n−1} + α_{n−2}, γ_2 = α_n + 2α_{n−1}\), we have: \(β_1 + β_2 = γ_1 + γ_2\), hence \(β_1 ∼ β_2\), but \(β_2 - β_1 = α_{n−1} + α_{n−2} ∈ Φ_s\). This is an example of case (2) of Proposition 4.9.

5. Triangulation orders

In this section we define some special orderings of abelian ideals, which we call triangulation orders, and prove that all facet ideals have a triangulation order. Throughout the section, let \(I\) be an abelian ideal of \(Φ^+\) such that \(\text{rk}(I) = n\). By “hyperplane”, we mean “linear hyperplane”.

Definition 5.1. Let \(J \subseteq I\). We say that \(J\) is bipartite if it has an initial section \(J_i\), and a final section \(J_f\) such that

1. \(J = J_i \cup J_f\);
2. for all \(\beta_1 \in J_i \setminus J_f\) and \(\beta_2 \in J_f \setminus J_i\), we have \(\beta_1 \not\lesssim \beta_2\);
3. there exists a hyperplane \(H\) in \(E\) such that \(J_i \cap J_f \subseteq H\) and \(H\) strictly separates \(J_i \setminus J_f\) from \(J_f \setminus J_i\).

If the above conditions hold, we say that \(\{J_i, J_f\}\) is a bipartition of \(J\). If, moreover, both \(J_i\) and \(J_f\) are proper subsets of \(J\), we say that \(\{J_i, J_f\}\) is a proper bipartition. A hyperplane \(H\) as in (3) is called a separating hyperplane, for the bipartition \(\{J_i, J_f\}\) of \(J\).

Note that, by definition, if \(J\) has a proper bipartition, then it has at least two elements. If \(J\) is also saturated, then it contains two crossing pairs and these provide at least three elements in \(J\). The definition also implies that, if \(\{J_i, J_f\}\) is a bipartition of \(J\), then \(J_i \setminus J_f\) and \(J_f \setminus J_i\) are an initial and a final section of \(J\), respectively, since the complement of an initial section is a final section, and vice-versa, and we have \(J = (J_i \setminus J_f) \cup J_f = J_i \cup (J_f \setminus J_i)\), where by \(\cup\) we denote disjoint union. Finally, we note that if \(J\) is saturated, also all the subsets \(J_i, J_f, J_i \setminus J_f, J_f \setminus J_i,\) and \(J_i \cap J_f\) are saturated.

Definition 5.2. For each subset \(S\) of \(\Phi^+\), we define the restricted relations \(\lesssim_S\) and \(\sim_S\) on \(S\) as follows. For all \(\beta_1, \beta_2 \in S\) we set:

1. \(\beta_1 \lesssim_S \beta_2\) if there exists a middle pair \(\{\gamma_1, \gamma_2\}\) between \(\beta_1\) and \(\beta_2\) contained in \(S\);
2. \(\beta_1 \sim_S \beta_2\) if either \(\beta_1 \lesssim_S \beta_2\), or \(\beta_2 \lesssim_S \beta_1\).

We say that \(S\) is \(\sim\)-closed if, for all \(\beta_1, \beta_2 \in S \cap \Phi^+\), \(\beta_1 \sim \beta_2\) implies \(\beta_1 \lesssim_S \beta_2\).

Obviously, for any \(S \subseteq \Phi^+\) and \(\beta_1, \beta_2 \in S\), the relation \(\beta_1 \lesssim_S \beta_2\) implies \(\beta_1 \lesssim \beta_2\). Hence, if \(S\) is \(\sim\)-closed, then, for all \(\beta_1, \beta_2 \in S\), we have \(\beta_1 \sim \beta_2\) if and only if \(\beta_1 \sim_S \beta_2\).

The first of following lemmas is clear, hence we omit the proof.

Lemma 5.3. Let \(S \subseteq \Phi^+\). If \(S\) is saturated, then \(S\) is \(\sim\)-closed.

Lemma 5.4. Let \(I\) be an abelian ideal in \(\Phi\), \(\Psi\) a root subsystem of \(\Phi\), and \(\Psi_1, \ldots, \Psi_k\) be the irreducible components of \(\Psi\). Moreover, let \(J\) be a \(\sim\)-closed subset of \(\Phi\) such that \(J \subseteq I \cap \Psi\), and let \(R \subseteq J\). Then, \(R\) is reduced in \(\Phi\) if and only if \(R \cap \Psi_i\) is reduced in \(\Psi_i\) for all \(i \in \{1, \ldots, k\}\).

Proof. The “only if” part is obvious. Conversely, we assume that \(R \cap \Psi_i\) is reduced in \(\Psi_i\) for all \(i \in \{1, \ldots, k\}\) and prove that \(R\) is reduced in \(\Phi\). By contradiction, let \(\beta_1 \lesssim \beta_2\) for some \(\beta_1, \beta_2 \in R\). Then, since \(J\) is \(\sim\)-closed, there exists a middle pair \(\{\gamma_1, \gamma_2\}\), between \(\beta_1\) and \(\beta_2\), contained in \(J\), hence in \(\Psi\). By Proposition 4.3(1), \((\beta_j, \gamma_j') > 0\) for all \(j, j' \in \{1, 2\}\), hence, there exists \(i \in \{1, \ldots, k\}\) such that \(\beta_j, \gamma_j \in \Psi_i\), for all \(j \in \{1, 2\}\). Thus, we have \(\beta_1 \lesssim_{\Psi_i} \beta_2\), contrary to the assumption.

Lemma 5.5. Let \(I\) be an abelian nilradical of \(\Phi^+\), \(\Psi\) a parabolic root subsystem of \(\Phi\), and \(\Pi\) the simple system of \(\Psi^+\). Assume that the following conditions hold:

(a) \(\Pi_\Psi \setminus I \subseteq \Pi\);
(b) if \(\Psi', \Psi''\) are distinct irreducible components of \(\Psi\), then \(I \cap \Psi'\) and \(I \cap \Psi''\) are element-wise incomparable.

Then \(I \cap \Psi\) is saturated, hence \(\sim\)-closed.

Proof. Let \(\gamma_1, \gamma_2 \in I \cap \Psi\) with \(\gamma_1 < \gamma_2\). Then \(\gamma_2 - \gamma_1\) is a linear combination of roots in \(\Pi\) with non-negative, integral, coefficients.
Let \( \Psi_1, \ldots, \Psi_k \) be the irreducible components of \( \Psi \) and \( \Pi_\Psi \), the simple system of \( \Psi_i \) for \( i = 1, \ldots, k \). By assumption (b), there exists \( i \in \{1, \ldots, k\} \) such that \( \gamma_1, \gamma_2 \in \Psi_i \).

By Proposition 3.5, \( I \cap \Psi_i \neq \emptyset \) if and only if there exists \( \beta_i^* \in I \cap \Pi_\Psi \). Moreover, in such a case, we have \( I \cap \Pi_\Psi = \{\beta_i^*\} \), and \( I \cap \Psi_i = \Psi_i \setminus \Phi(\Pi_\Psi \setminus \{\beta_i^*\}) \). It follows that \( \gamma_2 - \gamma_1 \) is a \( Z \)-linear combination of roots in \( \Pi_\Psi \setminus \beta_i^* \).

By assumption (a), \( \Pi_\Psi \setminus \beta_i^* \subseteq \Pi \), hence, being \( \Pi \) a linear basis of \( E \), \( \gamma_2 - \gamma_1 \) is a linear combination of roots in \( \Pi_\Psi \setminus \beta_i^* \) with non-negative integral coefficients. Since \( \Psi \), and hence \( \Psi_i \), is parabolic, we obtain that all \( \gamma \in \Phi \) such that \( \gamma_1 \leq \gamma \leq \gamma_2 \) belong to \( \Psi_i \), hence to \( I \cap \Psi_i \).

This proves that \( I \cap \Psi \) is saturated and hence, by Lemma 5.3, also \( \sim \)-closed. \( \Box \)

We recall that we have defined the set \( \Red(\beta) \), for \( \beta \in \Phi^+ \), in Definition 4.12.

**Definition 5.6.** Let \( J \subseteq I \), and \( \beta \in J \). We say that \( \beta \) is a detachable element in \( J \) if the following conditions hold:

1. \( \beta \) is an extremal element of \( J \) (with respect to the standard partial order);
2. there exists a hyperplane \( H \) such that:
   - (a) \( J \cap \Red(\beta) = J \cap H \) and \( H \) strictly separates \( \beta \) from \( J \setminus (\{\beta\} \cup \Red(\beta)) \);
   - (b) \( I \cap H \) is \( \sim \)-closed.

We call such a hyperplane \( H \) a detachable hyperplane for \( \beta \) in \( J \).

**Lemma 5.7.** Let \( I \) be a facet ideal, \( \beta \in I \cap \Phi_I \), and \( I(\beta^+) = \{\gamma \in I \mid (\gamma, \beta^+) = 1\} \). Let \( \alpha_I \) be the (unique) simple root such that \( I = \{\gamma \in \Phi \mid c_{\alpha_I}(\gamma) = m_{\alpha_I}\} \). Recall that \( \omega_{\alpha_I} \) is the fundamental coweight such that \( (\alpha_I, \omega_{\alpha_I}) = 1 \) and \( (\alpha, \omega_{\alpha_I}) = 0 \) for all \( \alpha \in \Pi \setminus \{\alpha_I\} \).

We set \( \nu = m_{\alpha_I}\beta^+ - \omega_{\alpha_I} \), and \( H = \nu^\perp \). Then, for all \( \gamma \in I \), we have \( (\nu, \gamma) = 0 \) if and only if \( (\beta^+, \gamma) = 1 \), hence \( I \cap H = I(\beta^+) \cap \Red(\beta) = I \cap H \).

Moreover, if \( J \) is such that \( J \subseteq I(\beta^+) \), and \( \beta \) is an extremal element of \( J \), then \( H \) is a detachable hyperplane for \( \beta \) in \( J \).

**Proof.** By Remark 4.13, \( I(\beta^+) \cap \Red(\beta) = \{\gamma \in I \mid (\gamma, \beta^+) = 1\} \). Let \( \alpha_I \) be the (unique) simple root such that \( I = \{\gamma \in \Phi \mid c_{\alpha_I}(\gamma) = m_{\alpha_I}\} \). Recall that \( \omega_{\alpha_I} \) is the fundamental coweight such that \( (\alpha_I, \omega_{\alpha_I}) = 1 \) and \( (\alpha, \omega_{\alpha_I}) = 0 \) for all \( \alpha \in \Pi \setminus \{\alpha_I\} \).

We set \( \nu = m_{\alpha_I}\beta^+ - \omega_{\alpha_I} \), and \( H = \nu^\perp \). Then, for all \( \gamma \in I \), we have \( (\nu, \gamma) = 0 \) if and only if \( (\beta^+, \gamma) = 1 \), hence \( I \cap H = I(\beta^+) \cap \Red(\beta) = I \cap H \).

Now, we prove that \( I \cap H \) is \( \sim \)-closed. Let \( \beta_1, \beta_2 \in \Phi^+ \cap H \), \( \beta_1 \sim \beta_2 \), and \( \{\gamma_1, \gamma_2\} \) be a middle pair between \( \beta_1 \) and \( \beta_2 \). Then \( (\gamma_1 + \gamma_2, \beta^+) = (\beta_1 + \beta_2, \beta^+) = 2 \). Since \( \beta \) is long, this forces \( (\gamma_1, \beta^+) = (\gamma_2, \beta^+) = 1 \), hence \( \{\gamma_1, \gamma_2\} \subseteq I \cap H \), which implies the claim.

It remains to prove the second assertion. Let \( J \subseteq I(\beta^+) \) and \( \beta \) be an extremal element in \( J \). Then, by the previous part, \( J \cap \Red(\beta) = I \cap H \). In order to prove that \( H \) is a detachable hyperplane for \( \beta \) in \( J \), it remains to prove that \( H \) strictly separates \( \beta \) from \( J \setminus (\{\beta\} \cup H) \). We prove that \( H \) strictly separates \( \beta \) from \( I \setminus (\{\beta\} \cup H) \), which implies the claim. Since \( I \) is abelian, we have \( (\beta^+, \gamma) \geq 0 \) for all \( \gamma \in I \). Moreover, we have \( (\beta^+, \gamma) \in \{0, \pm 1\} \), since \( \beta \in \Phi_I \). Therefore, for all \( \gamma \in I \setminus H \), we have \( (\beta^+, \gamma) = 0 \), hence \( (\nu, \gamma) = -m_{\alpha_I} \). Moreover, we have \( (\beta, \nu) = m_{\alpha_I} \), hence the claim is proved. \( \Box \)

**Definition 5.8.** Let \( \leq \) be a total order relation on \( I \), and

\[
S_{I, \leq} = \{\beta \in I \mid \rk(\beta^+ \leq \beta) = n\}.
\]

We say that \( \leq \) is a triangulation order if the following conditions hold:

1. \( I \setminus S_{I, \leq} \) is saturated;
2. for each \( \beta \in S_{I, \leq}, (\beta^+) \) is saturated and either one of the following conditions holds:
   - (a) \( \beta \) is detachable in \( (\beta^+) \),

(b) $(\beta \subseteq) \) has a bipartition $\{J_1, J_2\}$ such that, for both $J = J_1$ and $J = J_2$, $\beta$ is detachable in $J$.

**Remark 5.9.**

1. The definition directly implies that, for any total ordering $\preceq$ on $I$, the subset $S_I, \preceq$ is an initial section of the ordered set $(I, \preceq)$. Moreover, we have $\text{rk}(I \setminus S_I, \preceq) < n$.

2. The set $I \setminus S_I, \preceq$ may be properly contained in $I \setminus \text{Span}(I \setminus S_I, \preceq)$. For the triangulation orders that we will construct, this happens exactly in one case, namely for type $E_7$.

3. The above definition does not contain any condition on the restriction of $\preceq$ to $I \setminus S_I, \preceq$. Hence, if $\preceq$ is a triangulation order, any other total order $\preceq'$ such that $S_I, \preceq' = S_I, \preceq$, and $\preceq$ and $\preceq'$ coincide on the initial section $S_I, \preceq$, is a triangulation order, too.

We will prove the existence of triangulation orders for all facet ideals. The proof requires a case by case analysis. By Proposition 3.2, we may restrict the analysis to the abelian nilradicals.

**Definition 5.10.** We say that the facet ideal $I$ of $\Phi^+$ is an abelian nilradical of type $X_{n,k}$, and we write $I \cong X_{n,k}$, if there exists an irreducible root subsystem $\Psi$ of $\Phi$ and a positive system $\Psi^+$ of $\Psi$ such that:

1. $I$ is an abelian nilradical of $\Psi^+$;
2. $\Psi$ is of type $X_n$;
3. if $\{\alpha_1', \ldots, \alpha_n'\}$ is a simple system of $\Psi^+$, numbered according to Bourbaki’s conventions [2], then $I$ is the principal ideal generated by $\alpha_k'$ in $\Psi^+$.

It is implicit in the definition that the above $\alpha_k'$ has multiplicity 1 in $\Psi$.

We note that the type of a facet ideal may be not unique, if the root system $\Psi$ has nontrivial Dynkin diagram automorphisms. We identify the types $X_{n,k}$ and $X_{n,k'}$ if there exists a diagram automorphism that maps $\alpha_k$ into $\alpha_{k'}$. By a direct inspection of the highest root in all root types, we see that the possible abelian nilradicals types, in an irreducible root system of rank $n$, are the following:

$A_{n,k}$ for $k = 1, \ldots, n$, $B_{n,1}$, $C_{n,n}$, $D_{n,k}$ for $k = 1, n-1, n$, $E_{6,1}$, $E_{6,6}$, $E_{7,7}$.

Among them, we have the identifications: $A_{n,k} = A_{n, k'}$ for $k + k' = n + 1$; $D_{n,n-1} = D_{n,n}$ for all $n \geq 4$ and $D_{4,1} = D_{4,4}$; $E_{6,1} = E_{6,6}$.

By Proposition 3.2, the facet ideals that are not abelian nilradicals of $\Phi^+$ are in any case abelian nilradicals of some type. Their type $X_{n,k}$ is explicitly obtained as follows.

If the type of $\Phi$ is $A_n$, all the facet ideals are nilradicals of $\Phi^+$, hence we may assume that the extended Dynkin graph of $\Phi$ is a tree. Then, $I_{F_{n}}$ is a facet ideal of $\Phi^+$ if and only if $\alpha_1$ is a leaf in the extended Dynkin graph. By Corollary 2.9, the Dynkin graph obtained by removing $\alpha_i$ from the extended Dynkin graph of $\Phi$, gives the root type $X_n$. Moreover, the position of $-\theta$ in the new Dynkin graph gives the index $k$ of the abelian nilradical type $X_{n,k}$. Below, we write the resulting type for the facet ideals that are not abelian nilradicals of $\Phi^+$ itself. If the root type of $\Phi$ is $Y_n$, we write $I_{F}(Y_n, \alpha_i)$ in place of $I_{F_{n_i}}$:

$I_{F}(B_{n,1}, \alpha_i) \cong D_{n,n}$, $I_{F}(F_4, \alpha_4) \cong B_{4,1}$, $I_{F}(E_7, \alpha_2) \cong A_{7,1}$, $I_{F}(E_8, \alpha_1) \cong D_{8,1}$, $I_{F}(E_8, \alpha_2) \cong A_{8,1}$.

In proving the next proposition, we will consider, case by case, the seven possible distinct sporadic or classes of abelian nilradical types. The main points of the proof...
are illustrated in Figures 1–9. We first give some explanation of these figures. We may
arrange the roots of any facet ideal \( I \) in a matrix \((\beta_{i,j})\), in such a way that adjacent
entries differ by a simple root. The label \( i \) on a certain edge means that the difference
between its vertexes is the simple root \( \alpha_i \). We choose the matrix arrangement of roots
so that the standard partial order is compatible with the reverse lexicographic order
of row and column indexes, starting from \( \beta_{1,1} = \theta \). In this way, the matrix yields a
Hasse diagram of \( I \) in which the order ascends toward northwest. We note that this
condition does not determine a unique possibility. The figures illustrate the proof on
such Hasse diagrams for all the abelian nilradicals.

**Proposition 5.11.** Each facet ideal has a triangulation order.

**Proof.** By the above discussion, we may assume that \( I \) is an abelian nilradical of \( \Phi^+ \).

By Remark 5.9, it suffices to define a subset \( S_{I, \prec} \) of \( I \) and a partial order \( \preceq \) on
\( I \) that is total on \( S_{I, \prec} \) and has \( S_{I, \prec} \) as an initial section, in such a way that all
conditions of Definition 5.8 are satisfied. (In figures 1–9, the circled nodes correspond
to the elements in \( S_{I, \prec} \).)

Henceforth, we write \( S_I \) in place of \( S_{I, \prec} \) and we intend that \( S_I \) is an initial
section of \( \preceq \). We will define the restriction \((S_I, \preceq)\) as a sequence \((\beta_1, \ldots, \beta_k)\) (so that
\((\beta_\preceq^k) = (\beta_1, \ldots, \beta_k) \cup (I \setminus S_I))\). Then, we will find a hyperplane \( H \) such that
\( \text{Span}(I \setminus S_I) = H_I \) and \( \beta_k \not\in H_I \); this ensures that \( S_I \) is well defined, i.e. \( S_I = \{\beta \in I \mid \text{rk}(\beta^\preceq) = n\} \). Moreover, we will prove that \( I \setminus S_I \) is saturated (condition (1) of
Definition 5.8).

In all cases, the sequence \((\beta_1, \ldots, \beta_k)\) will be such that, for \( i = 1, \ldots, k \), \( \beta_i \) is
extremal in \((\beta_\preceq^i)\), with respect to the standard partial order. Since \( I \setminus S_I \) is saturated,
this implies that \((\beta_\preceq^k)\) is saturated and, by induction on \( k - 1 \), that \((\beta_\preceq^i)\) is saturated,
for \( i = 1, \ldots, k \). Therefore, in order to prove condition (2) of Definition 5.8, it will
remain to prove that either condition (a), or (b), holds for all \( \beta_i \).

If \( \beta_i \) is long and \( \beta_i = \min(\beta_\preceq^i) \), or \( \beta_i = \max(\beta_\preceq^i) \) (with respect to the standard
partial order), then \( \beta_i \) is detachable in \((\beta_\preceq^i)\) by Lemma 5.7 applied with \( J = (\beta_\preceq^i)\),
and we have nothing to prove. In the remaining cases, we will directly prove that
conditions (a) or (b) of Definition 5.8(2) hold.

Finally, since \( \beta_i \) is extremal in \((\beta_\preceq^i)\), in order to prove that \( \beta_i \) is detachable in \((\beta_\preceq^i)\),
or in a subset of its, it will suffice to check that condition (2) of Definition 5.6 holds.

Now we can give the details of the proof for each abelian nilradical. Throughout
the rest of the proof, we use the following notation: for \( h, k \in [h, k] \) is the interval
\( \{i \in \mathbb{Z} \mid h \leq i \leq k\} \). For all \( h \in [1, n] \) and \( S \subseteq [1, n] \), \( \omega_h = \omega_n \) and \( \alpha_S = \sum_{s \in S} \alpha_s \).

**A.** \( I \cong \Lambda_{n,k}, \left[ \frac{n}{2} \right] < k < n \). We recall that \( \Phi^+ = \{\alpha_{[j,i]} \mid 1 \leq i \leq j \leq n\} \), whence
\( I = \{\alpha_{[i,j]} \mid 1 \leq i \leq k \leq j \leq n\} \).

We define \((S_I, \preceq) = (\alpha_{[k,j]} \mid j = k, \ldots, n)\). Then, \( I \setminus S_I \) is the principal ideal
\((\alpha_{[k-1,k]}^\preceq)\) of \( \Phi^+ \), in particular is saturated. Let \( H_I = (\omega_k \sim \omega_{k-1})^\perp \). It is easily
seen that \( \text{Span}(I \setminus S_I) = H_I \) and \( \alpha_{[k,n]} \not\in H_I \), hence \( S_I \) is well defined.

It remains to prove that \( \beta \) is detachable in \((\beta_\preceq^i)\), for all \( \beta \in S_I \).

Let \( \beta = \alpha_{[j,i]} \) (\( j \in [k, n] \)) and \( H = (\omega_k - \omega_{k-1} - \omega_{j+1})^\perp \) (where \( \omega_{n+1} = 0 \)). It is
easy to check that \( \beta \) is minimal in \((\beta_\preceq^i)\). We prove that \( H \) is a detaching hyperplane
for \( \beta \) in \((\beta_\preceq^i)\). Let \( \Pi_1 = \{\alpha_1, \ldots, \alpha_{k-2}, \alpha_{[k-1,k]}, \alpha_{k+1}, \ldots, \alpha_n\} \) and, if \( j < n \), \( \Pi_2 = \{\alpha_{[j+1], k}, \alpha_{j+2}, \ldots, \alpha_n\} \) \{\( j > n \) \( \Pi_2 = \varnothing \). Then, \( \Pi_1 \cup \Pi_2 \) is the simple system
of \((\Phi \cap H)^\perp \), and \( \Phi \cap H = \Phi(\Pi_1) \cup \Phi(\Pi_2) \) is a decomposition into irreducible components
(both of type A). We have that \( I \cap \Phi(\Pi_1) \) is the principal ideal generated by \( \alpha_{[k-1,k]} \)
in \( \Phi(\Pi_1) \). Similarly, for \( j < n \), \( I \cap \Phi(\Pi_2) \) is the principal ideal generated by \( \alpha_{[k,j+1]} \).
in $\Phi(\Pi_2)$. It follows easily that $I \cap \Phi(\Pi_1)$ and $I \cap \Phi(\Pi_2)$ are pair-wise incomparable. Hence, we may apply Lemma 5.5 (with $\Psi = \Phi \cap H$) and obtain that $I \cap H$ is $\sim$-closed.

It remains to check that condition (2a) of Definition 5.6 holds. Let $\gamma \in (\beta^\leq)$. Looking at $\Pi_1$ and $\Pi_2$, we see that, if $\gamma \in H$, then either $\gamma$ and $\beta$ are incomparable for the standard partial order, or $\gamma - \beta \in \Phi^+$. If $\gamma \not\in H$, then $\gamma = \alpha_{[i,n]}$ with $i < k$ and $i' < j$, hence $\gamma \not\sim \beta$ and $\gamma - \beta \not\in \Phi$. By Corollary 4.10, we obtain that $\gamma \sim \beta$ if and only if $\gamma \not\in H$, which is the claim.

**Figure 1.** $I \cong A_{9,6}$, $\beta = \alpha_{[6,7]}$. The gray boxes cover the roots in $H = (\tilde{\omega}_6 - \tilde{\omega}_5 - \tilde{\omega}_9)^\perp$.

**C.** $I \cong C_{n,n}$. We recall that $\Phi^+ = \{\alpha_{[i,j]}^+, \alpha_{[i,n]} + \alpha_{[j,n-1]} \mid 1 \leq i \leq j \leq n\}$, hence $I = \{\alpha_{[i,n]} + \alpha_{[j,n-1]} \mid 1 \leq i \leq j \leq n\}$ (with $\alpha_{[n,n-1]} = 0$).

We define $(S_I, \approx) = (\alpha_{[i,n]} \mid i = n, n-1, \ldots, 1)$. Then, $I \setminus S_I$ is the principal ideal $(\alpha_n + 2\alpha_{n-1})$ of $\Phi^+$, in particular it is saturated. Let $H_I = (2\tilde{\omega}_n - \tilde{\omega}_{n-1})^\perp$. It is easily seen that Span$(I \setminus S_I) = H_I$ and $\alpha_{[1,n]} \not\in H_I$, hence $S_I$ is well defined.

Now, we prove that $\beta$ is detachable in $(\beta^\leq)$, for all $\beta \in S_I$.

Let $\beta = \alpha_{[j,n]}$, with $j \in [1,n]$. $H = (2\tilde{\omega}_n - \tilde{\omega}_{n-1} - \tilde{\omega}_{j-1})^\perp$. It is easy to check that $\beta$ is minimal in $(\beta^\leq)$. We prove that $H$ is a detecting hyperplane. Let $\Pi_1 = \{\alpha_n + 2\alpha_{n-1}\} \cup \{\alpha_1 \mid 1 \leq i \leq n-2\}$, if $j \leq n-1$, and $\Pi_1 = \varnothing$ if $j = n$. Moreover, let $\Pi_2 = \{\alpha_{[j,n]}\} \cup \{\alpha_1 \mid 1 \leq i \leq j-2\}$, if $j \leq 2$, and $\Pi_2 = \varnothing$ for $i = 1$. Then, $\Pi_1 \cup \Pi_2$ is a simple system for $\Phi \cap H$. Moreover, $\Phi \cap H = (\Phi(\Pi_1) \cup \Phi(\Pi_2))$ is a decomposition into irreducible components (of type C and A, respectively). It is easily seen that $\Phi(\Pi_1)$ and $\Phi(\Pi_2)$ are element-wise incomparable, hence, the conditions of Lemma 5.5 are satisfied, with $\Psi = \Phi \cap H$. It follows that $I \cap H$ is $\sim$-closed.

If $\gamma \in I$, then $\gamma = \alpha_{[k,h]} + \alpha_{[k,n-1]}$ for some $1 \leq h \leq k \leq n$. Hence, $\gamma \in H$ if and only if either $h \leq j - 1$ and $k = n$, or $j \leq h \leq k \leq n - 1$. In these cases, either $\gamma$ and $\beta$ are incomparable for the standard partial order, or $\gamma \not\sim \beta \in \Phi^+$. Moreover, if $\gamma \not\sim \beta \in \Phi^+$, then all $\gamma'$ such that $\gamma < \gamma' < \beta$ are short roots. Hence, in any case, $\gamma \not\sim \beta$, by Proposition 4.9(3). If $\gamma \in (\beta^\leq) \setminus H$, we have $\gamma = \alpha_{[h,n]} + \alpha_{[k,n-1]}$ with $h \leq j - 1 \leq k \leq n - 1$. Then, $\beta + \alpha_{[k,n-1]} \in \Phi$ and we obtain the crossing relation $\beta + \gamma = (\beta + \alpha_{[k,n-1]}) + \alpha_{[h,n]}$. It follows that $H$ satisfies the conditions of Definition 5.6, hence $\beta$ is detachable in $(\beta^\leq)$ (see Figure 2).

**B1 and D1.** $I \cong B_{n,1}$, or $I \cong D_{n,1}$. In case $B_{n,1}$, we have

$I = \{\alpha_{[1,i]} \mid 1 \leq i \leq n\} \cup \{\alpha_{[1,n]} + \alpha_{[j,n]} \mid 2 \leq j \leq n\}$.

In case $D_{n,1}$, we have

$I = \{\alpha_{[1,i]} \mid 1 \leq i \leq n\} \cup \{\tilde{\alpha}_{[1,n]} \} \cup \{\alpha_{[1,n]} + \alpha_{[j,n]} \mid 2 \leq j \leq n - 2\}$.
Figure 2. $I \cong C_{7,7}$, $\beta = \alpha_{[4,7]}$. The gray boxes cover the roots in $H = (2\tilde{\omega}_7 - \tilde{\omega}_3 - \tilde{\omega}_6)^\perp$.

where $\hat{\alpha}_{[1,n]} = \alpha_{[1,n]} - \alpha_{n-1}$.

We define $(S_I, \preceq) = (\alpha_1, \theta)$. Let $H_I = (\tilde{\omega}_2 - \tilde{\omega}_1)^\perp$. Then Span$(I \setminus S_I) = H_I$ and $\theta \not\in H_I$, hence $S_I$ is well defined. Since $S_I$ consists of the minimum and the maximum of $I$, we have that $I \setminus S_I$ is saturated.

Finally, for each $\beta \in S_I$, $\beta$ is either the minimum, or the maximum of $(\beta \preceq)$, with respect to the standard partial order, hence $\beta$ is detachable in $(\beta \preceq)$ by Lemma 5.7.

Figure 3. $I \cong B_{6,1}$ and $I \cong D_{6,1}$. In both cases, $S_I = \{\alpha_1, \theta\}$. The gray boxes cover the roots in $I \setminus S_I = I \cap H$, with $H = (\tilde{\omega}_1 - \tilde{\omega}_2)^\perp$.

Dn. $I \cong D_{n,n}$. Let $\hat{\alpha}_{[j,n]} = \alpha_{[j,n]} - \alpha_{n-1}$, for $1 \leq j \leq n - 1$. Then,

$I = \{\hat{\alpha}_{[j,n]} \mid 1 \leq j \leq n - 1\} \cup \{\alpha_{[j,n]} \mid 1 \leq j \leq n - 2\} \cup \{\alpha_{[i,n]} + \alpha_{[j,n-2]} \mid 1 \leq i < j \leq n - 2\}$.
We define \((S_I, \preceq) = (\hat{\alpha}_{[j,n]} | j = n, n - 2, \ldots, 1)\) and take \(H_I = (\hat{\omega}_n \setminus \hat{\omega}_{n-1})^\perp\). Then, \(I \setminus S_I\) is the principal ideal \((\alpha_{[n-2,n]}^\preceq)\) of \(\Phi^+\), hence it is saturated. Moreover, we have \(\text{Span}(I \setminus S_I) = H_I\) and \(\hat{\alpha}_{[1,n]} \notin H_I\), hence \(S_I\) is well defined.

It remains to prove that, for all \(\beta \in S_I\), either one or the other of conditions (a) and (b) of Definition 5.8 (2) is satisfied. If \(\beta = \alpha_n\) or \(\beta = \alpha_n + \alpha_{n-2}\), then \(\beta\) is the minimum of \((\beta^\preceq)\), hence it is detachable in \((\beta^\preceq)\) by Lemma 5.7. Then, let \(\beta = \hat{\alpha}_{[j,n]}\), with \(j \in \{1, \ldots, n - 3\}\). Let \(J_I = (\beta^\preceq)\). For \(j > 1\), let \(\theta_{j-1} = \alpha_{[j-1,n]} + \alpha_{[j,n-2]}\), and \(J_I = (\beta^\preceq) \setminus (\theta_{j-1})^\perp\) (see Figure 4). For \(j = 1\), let \(J_I = (\beta^\preceq)\): in this case \(J_I \subseteq J_I\). We prove that, for \(j > 1\), \((\beta^\preceq) = J_I \cup J_I\) is a proper bipartition. Indeed, we have: \((\beta^\preceq) = \{ \gamma \in I \mid c_{\alpha_j}(\gamma) \geq 1 \text{ or } c_{\alpha_{n-1}}(\gamma) \geq 1 \}\), \(J_I \setminus J_I = \{ \gamma \in I \mid c_{\alpha_j}(\gamma) = 0 \text{ and } c_{\alpha_{n-1}}(\gamma) = 1 \}\), and \(J_I \setminus J_I = \{ \gamma \in I \mid c_{\alpha_j}(\gamma) = 2 \}\) (note that \(c_{\alpha_j}(\gamma) = 2\) forces \(c_{\alpha_{n-1}}(\gamma) = 1\)). Hence, if we set \(H = (\hat{\omega}_n - \hat{\omega}_j)^\perp\), \(H\) strictly separates \(J_I \setminus J_I\) from \(J_I \setminus J_I\). Moreover, for any \(\gamma_1 \in J_I \setminus J_I\) and \(\gamma_2 \in J_I \setminus J_I\) we have \(c_{\alpha_j}(\gamma_2 - \gamma_1) = 2\) and \(c_{\alpha_{n-1}}(\gamma_2 - \gamma_1) = 0\). This implies \(\gamma_2 - \gamma_1 \notin \Phi\), hence \(\gamma_1 \lesssim \gamma_2\) by Proposition 4.9(1).

By definition, we have \(\beta = \min J_I\) hence we may apply Lemma 5.7 with \(J = J_I\) and obtain that \(\beta\) is detachable in \(J_I\).

The proof that \(\beta\) is also detachable in \(J_I\) is very similar to the proofs of cases \(A_n\) and 
\(C_n\). We take \(H^I = (\hat{\omega}_n - \hat{\omega}_{n-1} - \hat{\omega}_j)^\perp\), with \(\hat{\omega}_0 = 0\). Then, for each \(\gamma \in (\beta^\preceq)\), if \(\gamma \notin H^I\) and \(\gamma \neq \beta\), we have \(\gamma > \beta\) and \(\gamma, \beta \notin \Phi\). Hence, by Corollary 4.10, \(\gamma \sim \beta\) if and only if \(\gamma \notin H^I\). It remains to prove that \(I \cap H^I\) is \(\sim\)-closed. Indeed, let \(\Pi_1 = \{ \alpha_{[n-1,n]} \} \cup \{ \alpha_i \mid j \leq i \leq n - 2 \}\) \(\Pi_2 = \{ \hat{\alpha}_{[j-1,n]} \} \cup \{ \alpha_i \mid 1 \leq i \leq j - 2 \}\) \(\Pi_2 = \emptyset\) for \(j = 1\). Then, \(\Pi_1 \cup \Pi_2\) is a simple system for \(\Phi \cap H^I\), and \(\Phi \cap H^I = \Phi(\Pi_1) \cup \Phi(\Pi_2)\) is a decomposition into irreducible components (of types \(D\) and \(A\), respectively, for \(j > 1\)). For \(j = 1\) we have only the component \(\Phi(\Pi_1)\), which is irreducible of type \(D_{n-1}\). It is easy to see that \(I \cap \Phi(\Pi_1)\) and \(I \cap \Phi(\Pi_2)\) are pairwise incomparable, hence we may apply Lemma 5.5 with \(\Psi = \Phi \cap H^I\) and obtain that \(I \cap \Psi = I \cap H^I\) is \(\sim\)-closed.

\begin{figure}[h]
\centering
\includegraphics[width=0.7\textwidth]{diagram.png}
\caption{\(I \cong D_{8,8}\), \(\beta = \hat{\alpha}_{4,8}\). The gray boxes cover \((\beta^\preceq)\), partitioned according to the bipartition described in the proof.}
\end{figure}
E6. $I \cong E_{6,6}$. We choose 

$$(S_I, \preceq) = (\alpha_6, \theta, \alpha_{\{5,6\}}, \theta - \alpha_2, \alpha_{\{4,5,6\}}, \theta - \alpha_{\{2,4\}}, \alpha_{\{2,4,5,6\}}, \theta - \alpha_{\{2,4,5\}}).$$

The roots in $(S_I, \preceq)$ are all the $\gamma \in I$ with $c_{\alpha_3}(\gamma) = 0$, alternated with their symmetric roots with respect to the order involution, which are all the $\gamma \in I$ with $c_{\alpha_3}(\gamma) = 2$. Hence $I \setminus S_I$ is saturated.

Let $H_I = (\tilde{\omega}_8 - \tilde{\omega}_5)^\perp$. Then, $\text{Span}(I \setminus S_I) = H_I$ and $\theta - \alpha_{\{2,4,5\}} \notin H_I$, hence $S_I$ is well defined.

Let $\Pi' = \{\alpha_{\{3,6\}}\} \cup (I \setminus \{\alpha_3, \alpha_6\})$. Then $\Phi(\Pi')$ is irreducible, of type $A_5$, and $I \setminus S_I$ is the abelian nilradical generated by $\alpha_{\{3,6\}}$ in $\Phi(\Pi')$, of type $A_{5,2}$. Hence, $I \cap \text{Span}(I \setminus S_I)$ is $\preceq$-closed by Lemma 5.5 applied with $\Psi = \Phi(\Pi')$.

The first six $\beta$ in $(S_I, \preceq)$ are detachable in their $(\beta^\preceq)$ by Lemma 5.7, being either the minimum, or the maximum of $(\beta^\preceq)$. Hence, it remains to prove that the last two roots, $\beta = \alpha_{\{2,4,5,6\}}$ and $\beta' = \theta - \alpha_{\{2,4,5\}}$ are detachable in their $\preceq$-cone. We will prove that, in both cases, $H_I$ is a detaching hyperplane. We have $(\beta^\preceq) = \{\beta\} \cup (I \setminus S_I) \cup \{\beta'\}$. It is easy to check that, for all $\gamma \in I \setminus S_I$, either $\beta$ is incomparable with $\gamma$, or $\gamma - \beta \in \Phi^\perp$. Hence, by Corollary 4.10, $\beta \not\preceq \gamma$ for all $\gamma \in I \setminus S_I$. For $\beta'$, we have $\beta \leq \beta'$ and $\beta' - \beta \notin \Phi$, hence $\beta \leq \beta'$. Now, $H_I$ strictly separates $\beta$ from $\beta'$ since $c_{\alpha_3}(\beta) = 0$ and $c_{\alpha_3}(\beta') = 2$. Moreover, we have already seen that $I \setminus S_I$ is equal to $I \cap H_I$ and is saturated, hence $\sim$-closed. It follows that $\beta$ is detached in $(\beta^\preceq)$, with detaching hyperplane $H_I$. For $\beta'$, the proof is similar (see Figure 6).

E7. $I \cong E_{7,7}$. We recall that $\theta = 2\alpha_1 + 2\alpha_2 + 3\alpha_3 + 4\alpha_4 + 3\alpha_5 + 2\alpha_6 + \alpha_7$. The order involution maps $\alpha_2$ and $\alpha_4$ onto their opposite roots, $\alpha_7$ onto $\theta$, and the sequence $(\alpha_1, \alpha_3, \alpha_5, \alpha_6)$ onto $(-\alpha_6, -\alpha_5, -\alpha_3, -\alpha_1)$. 

**Figure 5.** $I \cong D_{8,8}$. $\beta = \tilde{\alpha}_{4,8}$. The diagram represents $(\beta^\preceq)$. The big rectangle contains the roots in $J_i$ and the gray parts cover the roots in $H^\perp = (\tilde{\omega}_8 - \tilde{\omega}_7 - \tilde{\omega}_3)^\perp$. 
For any $\gamma \in I$, we denote by $\gamma'$ the symmetric of $\gamma$ with respect to the order involution and we define

$$(S_I, \preceq) = (\alpha_7, \alpha'_7, \alpha_{(6,7)}, \alpha'_{(6,7)}, \alpha_{(5,6,7)}, \alpha'_{(5,6,7)}, \alpha_{(4,5,6,7)}, \alpha'_{(4,5,6,7)}, \alpha_{(2,4,5,6,7)}, \alpha'_{(2,4,5,6,7)}).$$

By definition, $(S_I, \preceq)$ consists of all $\beta$ in $I$ such that $c_{\alpha_7}(\beta) + c_{\alpha_4}(\beta) \leq 1$, together with their symmetric roots (see Figure 7). Then, we have $\min(I \setminus S_I) = \alpha_{[2,7]}$, hence $\max(I \setminus S_I) = \alpha'_{[2,7]}$. In particular, $I \setminus S_I$ is a root interval, hence it is saturated.

Let $H_I = (\tilde{\omega}_7 - \tilde{\omega}_2)^\perp$ and let $\beta = \alpha_{(2,4,5,6,7)}$. We can directly check that $H_I \cap I = (I \setminus S_I) \cup \{\beta, \beta'\}$. We have $\beta, \beta' \in S_I$, nevertheless, $\Span(I \setminus S_I) = H_I$. Moreover, $\max_{\preceq} S_I = \alpha'_{[1,3,4,5,6]} = \theta - \alpha_{[1,3,4,5,6]} \notin H_I$. Hence, $S_I$ is well defined (see Figure 7).

All roots in $S_I$, except $\beta = \alpha_{(2,4,5,6,7)}$, $\eta = \alpha_{[1,3,4,5,6]}$ and their symmetric roots, are either the minimum, or the maximum of their $\preceq$-upper cone, with respect to the standard partial order, so they are detachable in it by Lemma 5.7. It remains to consider $\beta, \beta', \eta, \eta'$.

First, we find a bipartition of $(\beta^\perp)$ that satisfies the requirements of Definition 5.8(2). Let $J_1 = (\beta^\perp) \cap (\beta^\perp) = \{\gamma \in (\beta^\perp) \mid c_{\alpha_2}(\gamma) \geq 1\}$ and $J_1 = \{\gamma \in (\beta^\perp) \mid c_{\alpha_2}(\gamma) \leq 1\}$. It is easily seen that $J_1 \cap J_1 = I \cap H_I$ and that $H_I$ strictly separates $J_1 \setminus J_1$ from $J_1 \setminus J_1$. Moreover, we can directly check that, for all $\gamma_1 \in J_1 \setminus J_1$ and $\gamma_2 \in J_1 \setminus J_1$, we have $\gamma_2 - \gamma_1 \in L^+(\Phi) \setminus \Phi^+$, hence $\gamma_1 \leq \gamma_2$. It remains to check that $\beta$ is detachable in $J_1$ and $J_1$. For $J_1$ this follows from Lemma 5.7, since $\beta = \min_{\preceq} J_1$. For $J_1$, we prove that the hyperplane $H^1 = (\tilde{\omega}_7 - \tilde{\omega}_3)^\perp$ is a detachable hyperplane. Indeed, $(\Phi \cap H^1)$ is an irreducible root subsystem of type $A_6$, with simple system $\{\alpha_{[3,7]}\} \cup \Pi \setminus \{\alpha_7, \alpha_3\}$. Hence, we may apply Lemma 5.5, with $\Psi = \Phi \cap H^1$, and find that $I \cap H^1$ is $\sim$-closed (see also Figure 8). Moreover, we can directly check that, for all $\gamma \in J_1 \cap H^1$, either $\gamma$ and $\beta$ are incomparable, or $\gamma - \beta \in \Phi^+$, hence $\gamma \not\sim \beta$. Finally, for all $\gamma \in J_1 \setminus H^1$, we have $\gamma > \beta$ and $\gamma - \beta \notin \Phi$, hence, by Corollary 4.10, $\gamma \sim \beta$. Hence $H^1$ is a detachable hyperplane for $\beta$ in $J_1$ (see Figure 8).

The case of $\beta'$ is similar to the previous one, by symmetry.

It remains to deal with $\eta$ and $\eta'$. In this case, $H_I$ is a detachable hyperplane for $\eta$ in $(\eta^\perp)$ as well as for $\eta'$ in $(\eta'^\perp)$ (see Figure 9). Indeed, it is easily checked that for
Figure 7. $I \cong E_{7,7}$, $\beta = \alpha_{\{2,4,5,6,7\}}$. The gray rectangles illustrate the bipartition of $(\beta^\equiv)$. For the symmetric root $\beta' = \theta - \alpha_{\{1,4\}}$, the bipartition of $(\beta'^\equiv)$ is similar.

Figure 8. $I \cong E_{7,7}$, $\beta = \alpha_{\{2,4,5,6,7\}}$. The diagram represents $(\beta^\equiv)$. The big rectangle contains the roots in $J_i$ and the gray part covers the roots in $H_i = (\check{\omega}_7 - \check{\omega}_3)^\perp$. 
all $\gamma \in (\eta \sim) \cap H_I$, either $\gamma$ is incomparable with $\eta$ and $\eta'$, or $\gamma - \eta, \gamma - \eta' \in \Phi$. Hence $\gamma \not\sim \eta, \eta'$. Moreover, $(\eta \sim) \setminus H_I = \{\eta, \eta'\}$, $H_I$ separates $\eta$ from $\eta'$, and $\eta \sim \eta'$. Finally, $(\eta' \sim) \setminus H_I = \{\eta'\}$. This concludes the proof. \hfill \Box

\caption{\small $I \cong E_{7,7}, \gamma = \alpha_{\{1,3,4,5,6,7\}}$. The diagram represents $(\eta \sim)$. The gray square covers the roots contained in $H_I = (\tilde{\omega}_7 - \tilde{\omega}_2)^\perp$.}
\end{figure}

6. Triangulations of standard parabolic facets

In this section we prove Theorems 1.1 and 1.2.

Let $I$ be a face ideal of $\Phi^+$ and $F_I = \text{Conv}(I)$ be the corresponding standard parabolic face. For all $J \subseteq I$, let

$$\mathcal{R}_J = \{ R \subseteq J \mid R \text{ reduced} \}.$$ 

Then, let

$$\mathcal{T}_I = \{ \text{Conv}(R) \mid R \in \mathcal{R}_I, R \text{ maximal in } \mathcal{R}_I \}.$$ 

We will prove that $\mathcal{T}_I$ is a triangulation of $F_I$.

By Propositions 3.1 and 3.2, it suffices to prove the claim when $I$ is an abelian nilradical of $\Phi^+$. Henceforward, we make this assumption. So, there exists a unique simple root $\alpha_I \in \Pi$ such that $m_{\alpha_I} = 1$ and $I = (\alpha_I \sim)$. In particular, $I$ is a facet ideal and $F_I$ is a facet of $\mathcal{P}$.

The proof is by induction on $\text{rk}(\Phi)$ and is based on the existence of triangulation orders for all facet ideals. We start with two key lemmas.

For each $J \subseteq I$ let $\text{Cone}(J)$ be the positive cone generated by $J$, i.e. the set of linear combinations of elements in $J$ with nonnegative real coefficients. Moreover, let $[J]$ be the saturation of $J$, i.e.

$$[J] = \{ x \in I \mid \exists y, z \in J \text{ } y \leq x \leq z \}.$$
Lemma 6.1. Let $J$ be a saturated subset of $I$, and $\{J_1, J_2\}$ be a bipartition of $J$. Then $\text{Cone}(J) = \text{Cone}(J_1) \cup \text{Cone}(J_2)$.

Proof. The claim is obvious if the bipartition is not proper, in particular if $|J| \leq 2$. The inclusion $\text{Cone}(J_1) \cup \text{Cone}(J_2) \subseteq \text{Cone}(J)$ is clear in all cases. We prove the reverse inclusion by induction on $|J|$. It is easily seen that, for any $K \subseteq J$, $\{K \cap J_1, K \cap J_2\}$ is a bipartition of $K$. Therefore, it suffices to prove that if the bipartition $\{J_1, J_2\}$ of $J$ is proper, there exists a proper saturated subset $K$ of $J$ such that $x \in \text{Cone}(K)$.

So, let $J_1, J_2 \subseteq J$, $x \in \text{Cone}(J)$, and $x = \sum_{\beta \in J} c_\beta \beta$, with $c_\beta$ nonnegative real coefficients, be a fixed expression of $x$. If $\{\beta \in J \mid c_\beta > 0\}$ is included in $J_1$ or $J_2$ we are done. Also if the saturation $\{\beta \in J \mid c_\beta > 0\}$ is properly included in $J$ we are done. Hence, we assume $J = \{\beta \in J \mid c_\beta > 0\}$. This means that, for all $\beta \in \text{Min} J \cup \text{Max} J$, $c_\beta > 0$. Since $J_1 \setminus J_2$ and $J_2 \setminus J_1$ are an initial and a final section of $J$, we have $\text{Min}(J_1 \setminus J_2) \subseteq \text{Min} J$ and $\text{Max}(J_2 \setminus J_1) \subseteq \text{Max} J$. We fix $\beta_1 \in \text{Min}(J_1 \setminus J_2)$ and $\beta_2 \in \text{Max}(J_2 \setminus J_1)$. By Definition 5.1, and since $J$ is saturated, there exist $\gamma_1, \gamma_2 \in J$ such that $\beta_1 + \beta_2 = \gamma_1 + \gamma_2$ and $\beta_1 < \{\gamma_1, \gamma_2\} < \beta_2$. Hence, $c_{\beta_1} \beta_1 + c_{\beta_2} \beta_2 = (c_{\beta_1} - c_{\beta_2}) \beta_1 + c_{\beta_2} (\gamma_1 + \gamma_2) = (c_{\beta_2} - c_{\beta_1}) \beta_2 + c_{\beta_1} (\gamma_1 + \gamma_2)$. We obtain that, if $c_{\beta_1} > c_{\beta_2}$, then $x \in \text{Cone}(J \setminus \{\beta_2\})$, while, if $c_{\beta_2} < c_{\beta_1}$, then $x \in \text{Cone}(J \setminus \{\beta_1\})$. Since $\beta_1$ and $\beta_2$ are extremal elements in $J$, $\gamma_1$ and $\{\beta_1\}$ and $\{\beta_2\}$ are saturated, hence the claim is proved. □

Lemma 6.2. Let $J$ be a saturated subset of $I$, $\beta^* \in J$, $\beta^*$ detachable in $J$, and $J_\beta^* = \{\beta^*\} \cup (\text{Red}(\beta^*) \cap J)$. Then, $\text{Cone}(J) = \text{Cone}(J_\beta^*) \cup \text{Cone}(J \setminus \{\beta^*\})$.

Proof. Let $J' = J \setminus \text{Red}(\beta^*)$. Then, $\text{Cone}(J) = \text{Cone}(J') + \text{Cone}(\text{Red}(\beta^*) \cap J) \subseteq \text{Cone}(J') + \text{Cone}(J_\beta^*)$. Hence, it suffices to prove that $\text{Cone}(J') \subseteq \text{Cone}(J_\beta^*) \cup \text{Cone}(J \setminus \{\beta^*\})$.

Let $x \in \text{Cone}(J')$, $K = \{x \in \text{Cone}(K) \mid K \subseteq J' \} \in \text{Cone}(J')$, and $d = \min\{||K|| \mid K \in K\}$, where $[K]$ is the saturation of $K$ and $||K||$ its cardinality. Then, fix a $K \in K$ with $||K|| = d$ and let $x = \sum_{\beta \in K} c_\beta \beta$, with $c_\beta \geq 0$, be a fixed expression of $x$.

If $\beta^* \notin K$, $K \subseteq J \setminus \{\beta^*\}$ and we are done. Hence, let $\beta^* \in K$. We will prove that then $K = \{\beta^*\}$, which yields the claim, since $\{\beta^*\} \subseteq J_\beta^*$. By assumption, $\beta^*$ is extremal in $J$ hence in $K$. By symmetry, we may assume, without loss of generality, that $\beta^*$ is minimal in $K$. Then, let $\beta$ be a maximal element in $K$. If $\beta \neq \beta^*$, then, by definition of $J'$, we have $\beta^* \lesssim \beta$, hence there exists a middle pair $\{\gamma_1, \gamma_2\}$ between $\beta^*$ and $\beta$. If $c_{\beta^*} \geq c_{\beta}$, we have $c_{\beta^*} \beta^* + c_{\beta} \beta = (c_{\beta^*} - c_{\beta}) \beta^* + c_{\beta} (\beta^* + \beta) = (c_{\beta^*} - c_{\beta}) \beta^* + c_{\beta} (\gamma_1 + \gamma_2)$, hence $x \in \text{Cone}(K \setminus \{\beta^*\})$. This contradicts the minimality of $||K||$, since $[K] \setminus \{\beta^*\} = [K \setminus \{\beta^*\}]$. Similarly, if $c_{\beta^*} < c_{\beta}$, we obtain $x \in \text{Cone}(K \setminus \{\beta^*\})$, contrary to the minimality of $||K||$. □

Proposition 6.3. For all $J \subseteq I$, if $J$ is saturated, then

$$\text{Cone}(J) = \bigcup \{\text{Cone}(R) \mid R \subseteq J, R \text{ reduced}\}.$$ 

Proof. The claim is obvious if $\text{rk}(\Phi) = 1$. We assume $\text{rk}(\Phi) \geq 2$ and the claim holds for any abelian nilradical in any irreducible root system of rank strictly lower than $\text{rk}(\Phi)$.

Let $J \subseteq I$ be saturated. The inclusion “$\supseteq$” is clear, so it suffices to prove the reverse one. We assume $x \in \text{Cone}(J)$ and prove that there exists a reduced subset $R$ of $J$ such that $x \in \text{Cone}(R)$.

Let $\preceq$ be a triangulation order on $I$. We distinguish two cases.

(a) First, we consider the case $J \subseteq I \setminus S_{I, \rho}$. Let $\{c_\beta \mid \beta \in J\}$ be a fixed set of nonnegative real coefficients such that $x = \sum_{\beta \in J} c_\beta \beta$. Let $\Psi = \Phi \cap \text{Span}(I \setminus S_{I, \rho})$,
$\Psi_1, \ldots, \Psi_k$ be the irreducible components of $\Psi$, $I_i = I \cap \Psi_i$, $J_i = J \cap \Psi_i$. Let $x_i = \sum_{\beta \in J_i} c_{i\beta}\beta$, for $i = 1, \ldots, k$. Then, for all $i \in \{1, \ldots, k\}$, $I_i$ is an abelian nilradical of $\Psi_i$ and $J_i$ is saturated in $\Psi_i$. Hence, by the induction assumption, there exists a subset $R_i$ of $J_i$, reduced relatively to $\Psi_i$, such that $x_i \in \text{Cone}(R_i)$. Let $R = R_1 \cup \cdots \cup R_k$.

Now, $R \subseteq J$ and $J$ is $\sim$-closed, being saturated, hence, by Lemma 5.4, $R$ is reduced in $\Phi$. Since $x \in \text{Cone}(R)$, we are done.

(b) Now, we consider the case $J \not\subseteq I \cap S_{I_1, \varepsilon}$. Let $\beta_0 = \max_{\varepsilon_0} \{\beta \in J \mid x \in \text{Cone}(J \cap (\beta\varepsilon))\}$.

If $\beta_0 \not\in S_{I_1, \varepsilon}$, then $x \in \text{Cone}(J \cap (I \setminus S_{I_1, \varepsilon}))$. Since $J \cap (I \setminus S_{I_1, \varepsilon})$ is saturated, being the intersection of two saturated sets, we are reduced to case (a).

Then, we assume $\beta_0 \in S_{I_1, \varepsilon}$. In this case, $(\beta_0\varepsilon)$ is saturated (by Definition 5.8 (2)), hence, $J \cap (\beta_0\varepsilon)$ is saturated. It suffices to prove that there exists a reduced subset $R$ contained in $J \cap (\beta_0\varepsilon)$ such that $x \in \text{Cone}(R)$. By definition of triangulation order, either $\beta_0$ is detachable in $(\beta_0\varepsilon)$, or $(\beta_0\varepsilon)$ has a bipartition $\{B_1, B_1\}$ such that $\beta_0$ is a detachable element in both of $B_1$ and $B_2$. In the first case, we set $R = (\beta_0\varepsilon)$. In the latter case, $\{J \cap B_1, J \cap B_2\}$ is a bipartition of $J \cap (\beta_0\varepsilon)$ and, by Lemma 6.1, we may choose a $B \in \{B_1, B_2\}$ such that $x \in \text{Cone}(J \cap B)$.

In both cases, we set $J' = J \setminus B$. Then $J'$ is saturated, since $J$ and $B$ are. Moreover, $\beta_0 = \min_{\varepsilon} J'$, hence, by definition of $\beta_0$, in any expression of $x$ as a nonnegative linear combination of elements of $J'$, the coefficient of $\beta_0$ is strictly positive. Since $\beta_0$ is detachable in $B$, there exists a detaching hyperplane $H$ for $\beta_0$ in $B$. Then, such an $H$ is a detaching hyperplane also for $\beta_0$ in $J'$. By Lemma 6.2, we obtain $\text{Cone}(J') = \text{Cone}(\{\beta_0\} \cup (J' \setminus H)) \cup \text{Cone}(J' \setminus \{\beta_0\})$, hence $x \in \text{Cone}(\{\beta_0\} \cup (J' \setminus H))$.

Thus, there exists a positive real $c_0$ such that $x - c_0\beta_0 \in \text{Cone}(J' \setminus H)$. Now, $J' \cap H$ is contained in the abelian nilradical $I \cap H$ of $(\Phi \cap H)$. Let $\Psi_1, \ldots, \Psi_k$ be the irreducible components of $\Phi \cap H$. Arguing as in case (a), we find $R_1, \ldots, R_k$ such that $R_i \subseteq J' \cap \Psi_i$, $R_i$ is reduced relatively to $\Psi_i$, and $x - c_0\beta_0 \in \text{Cone}(R_1 \cup \cdots \cup R_k)$. Let $R' = R_1 \cup \cdots \cup R_k$. Then, since $R' \subseteq I \cap H$ and $I \cap H$ is $\sim$-closed, we have that $R'$ is reduced in $\Phi$, by Lemma 5.4. Moreover, by definition of $\beta_0$, we have $R' \subseteq (\beta_0\varepsilon)$, hence $R' \subseteq (\beta_0\varepsilon) \cap H$. By Definition 5.6, $(\beta_0\varepsilon) \cap H \subseteq \text{Red}(\beta_0)$, hence $R = (\{\beta_0\} \cup R')$ is reduced. This proves the claim, since $x \in \text{Cone}(R)$. \hfill $\square$

**Remark 6.4.** For each face $F_\alpha$ and $J \subseteq I_{F_\alpha}$, we have $\text{Cone}(J) \cap F_\alpha = \text{Cone}(J)$, since $(\sum_{\beta \in J} c_{\beta\alpha} \beta_\alpha) = \sum_{\beta \in J} c_{\beta}(\beta, \beta_\alpha) = \sum_{\beta \in J} c_{\beta} m_\alpha = m_\alpha$ if and only if $\sum_{\beta \in J} c_{\beta} = 1$.

**Corollary 6.5.** Let $T'_I = \{\text{Conv}(R) \mid R \in R_I, \text{rk}(R) = n\}$.

Then $T'_I$ is a covering of $F_I$.

**Proof.** By Proposition 6.3 and the above remark, the set of all $\text{Conv}(R)$, with $R \subseteq I$ and $R$ reduced, is a covering of $F_I$. By standard topological arguments, we obtain that also $T'_I$ is a covering of $F_I$. \hfill $\square$

Our next step is to prove that the set $T'_I$ defined in Corollary 6.5 is a triangulation of the standard parabolic facet $F_I$. For this, it remains to prove that each $T \in T'_I$ is a simplex, and that the intersection of any two $T_1, T_2 \in T_I$ is a common face of $T_1$ and $T_2$. This is proved in next two propositions.

**Proposition 6.6.** Let $R$ be a reduced subset of $I$. Then $R$ is linearly independent.
Proof. We prove the claim by induction on \( \text{rk}(\Phi) \). The case \( \text{rk}(\Phi) = 1 \) is obvious. We assume \( \text{rk}(\Phi) > 1 \) and the claim true for irreducible root systems of rank less than \( \text{rk}(\Phi) \). Let \( \preceq \) be a triangulation order on \( I \) and \( \beta = \min_\preceq R \).

First, we consider the case \( \text{rk}(\beta_\preceq) = n \) and \( \beta \) detachable in \( (\beta_\preceq) \). Let \( H \) be a detaching hyperplane for \( \beta \) in \( (\beta_\preceq) \). \( \Psi_1, \ldots, \Psi_k \) be the irreducible components of \( \Phi \cap H \), and \( R_i = (R \setminus \{\beta\}) \cap \Psi_i \), for \( i = 1, \ldots, k \). Then, \( R_i \) is contained in the abelian nilradical \( I \cap \Psi_i \) of \( \Psi_i \) and is reduced, relatively to \( \Psi_i \). By the induction assumption, \( R_i \) is linearly independent, for \( i = 1, \ldots, k \). Since \( R \setminus \{\beta\} = R_1 \cup \cdots \cup R_k \) and \( \beta \notin H \), we obtain that \( R \setminus \{\beta\} \) and \( R \) are linearly independent, too.

If \( \text{rk}(\beta_\preceq) = n \) and \( \beta \) is not detachable in \( (\beta_\preceq) \), there exists a bipartition \( \{J_1, J_2\} \) of \( (\beta_\preceq) \) such that \( \beta \) is a detachable element both in \( J_1 \), and in \( J_2 \). By Definition 5.1, either \( R \subseteq J_1 \), or \( R \subseteq J_2 \), hence we can argue as in the previous case.

If \( \text{rk}(\beta_\preceq) < n \), then \( R \) is contained in the abelian nilradical \( I \cap \text{Span}(I \setminus S_{I, \preceq}) \), in \( \Phi \cap \text{Span}(I \setminus S_{I, \preceq}) \) and we may argue by induction as above.

\( \square \)

**Proposition 6.7.** Let \( R_1, R_2 \) be reduced subsets in \( I \). Then, \( \text{Conv}(R_1) \cap \text{Conv}(R_2) = \text{Conv}(R_1 \cap R_2) \). In particular, \( \text{Conv}(R_1) \cap \text{Conv}(R_2) \) is a common face of \( \text{Conv}(R_1) \) and \( \text{Conv}(R_2) \).

**Proof.** By Proposition 6.6, \( \text{Conv}(R_i) \) is the simplex with set of vertexes \( R_i \), for \( i = 1, 2 \), hence \( \text{Conv}(R_1 \cap R_2) \) is common face of \( \text{Conv}(R_1) \) and \( \text{Conv}(R_2) \). Hence, it suffices to prove the first statement. The inclusion \( \text{Conv}(R_1) \cap \text{Conv}(R_2) \supseteq \text{Conv}(R_1 \cap R_2) \) is clear. We prove the reverse one, by induction on \( \text{rk}(\Phi) \).

If \( \text{Cone}(R_1) \cap \text{Cone}(R_2) \subseteq \text{Cone}(R_1 \cap R_2) \), then, by Remark 6.4, the analogous relation for the convex hulls holds. So we work with cones.

For \( \text{rk}(\Phi) = 1 \) the claim is obvious. Let \( \text{rk}(\Phi) > 1 \), \( \preceq \) be a triangulation order on \( I \), and \( \beta = \min_\preceq R_1 \cup R_2 \). We may assume \( \beta \in R_1 \).

(a) If \( \text{rk}(\beta_\preceq) < n \), then \( R_1, R_2 \subseteq I \setminus S_{I, \preceq} \). Let \( \Psi_1, \ldots, \Psi_k \) be the connected components of \( \Phi \cap \text{Span}(I \setminus S_{I, \preceq}) \), and \( R_{j,i} = R_j \cap \Psi_i \), for \( j = 1, 2 \) and \( i = 1, \ldots, k \). Each \( R_{j,i} \) is a reduced subset in the abelian nilradical \( I \cap \Psi_i \) of \( \Psi_i \), hence by the induction assumption \( \text{Cone}(R_{1,i}) \cap \text{Cone}(R_{2,i}) \subseteq \text{Cone}(R_{1,i} \cap R_{2,i}) \), for each \( i \in \{1, \ldots, k\} \). This easily implies the inclusion \( \text{Cone}(R_1) \cap \text{Cone}(R_2) \subseteq \text{Cone}(R_1 \cap R_2) \).

(b) Next, let \( \text{rk}(\beta_\preceq) = n \), \( \beta \) be detachable in \( (\beta_\preceq) \). \( H \) be a detaching hyperplane, and \( \overrightarrow{R} = R_1 \cap H \) for \( i = 1, 2 \). Let \( H^+ \) and \( H^- \) be the open and closed half spaces determined by \( H \) in \( E \). By Definition 5.6, \( \beta \) belong either to \( H^+ \), or to \( H^- \). We may assume \( \beta \in H^+ \), without loss of generality. Then \( (\beta_\preceq) \setminus \{\beta\} \subseteq \overrightarrow{H} \), and, if \( \gamma \in (\beta_\preceq) \cap H^- \), then \( \beta \sim \gamma \). It follows that, for a fixed \( i \in \{1, 2\} \), either \( R_i \subseteq \overrightarrow{H} \), or \( R_i \subseteq \overleftarrow{H} \). This implies \( \text{Cone}(R_i) \cap H = \text{Cone}(\overrightarrow{R_i}) \). Moreover, since we are assuming \( \beta \in R_1 \), we have then \( R_1 \subseteq \overrightarrow{H} \), and \( R_1 \setminus \{\beta\} = \overrightarrow{R_1} \). Now, we distinguish two subcases.

(b1) Let \( \beta = \min_\preceq R_1 < \min_\preceq R_2 \). Then, \( R_2 \subseteq \overleftarrow{H} \), hence \( R_1 \) and \( R_2 \) are weakly separated by \( H \). It follows easily that \( R_1 \cap R_2 = \overrightarrow{R_1} \cap \overrightarrow{R_2} \) and \( \text{Cone}(R_1) \cap \text{Cone}(R_2) = \text{Cone}(\overrightarrow{R_1} \cap \overrightarrow{R_2}) \).Arguing as in case (a), with \( \Phi \cap H \) in place of \( \Phi \cap \text{Span}(I \setminus S_{I, \preceq}) \) and \( \overrightarrow{R} \) in place of \( R_1 \), by the induction assumption we obtain \( \text{Cone}(\overrightarrow{R}) \cap \text{Cone}(\overrightarrow{R}) \subseteq \text{Cone}(\overrightarrow{R} \cap \overrightarrow{R}) \), and hence the claim.

(b2) Let \( \beta = \min_\preceq R_1 = \min_\preceq R_2 \). Then both \( R_1 \) and \( R_2 \) are contained in \( \overrightarrow{H} \), and, for all \( x \in \text{Cone}(R_1) \cap \text{Cone}(R_2) \), there exist \( c_i \in R \) and \( \overrightarrow{x}_i \in \text{Cone}(\overrightarrow{R}) \) \( (i = 1, 2) \) such that \( x = c_1 \beta + \overrightarrow{x}_1 = c_2 \beta + \overrightarrow{x}_2 \). Since \( \overrightarrow{x}_1, \overrightarrow{x}_2 \in H \) and \( \beta \notin H \), we must have \( c_1 = c_2 \) and hence \( \overrightarrow{x}_1 = \overrightarrow{x}_2 \). It follows \( \overrightarrow{x}_1 \in \text{Cone}(\overrightarrow{R} \cap \overrightarrow{R}) \) and hence \( x \in \text{Cone}(R_1 \cap R_2) \).

(c) Finally, let \( \text{rk}(\beta_\preceq) = n \), \( \beta \) not be detachable in \( (\beta_\preceq) \), and \( \{J_1, J_2\} \) be a bipartition of \( (\beta_\preceq) \). By definition, each of \( R_1 \) and \( R_2 \) is contained in exactly one of \( J_1 \) and \( J_2 \). If both are contained in \( J_i \), or both in \( J_j \), we are reduced to case (b). Otherwise, we may
assumee \( R_1 \subseteq J_i, R_2 \subseteq J_i, R_1 \cap (J_i \setminus J_i) \neq \emptyset, \) and \( R_2 \cap (J_i \setminus J_i) \neq \emptyset. \) Let \( H \) be a separating hyperplane for the bipartition \( \{ J_i, J_i \} \), and \( \mathcal{R}_i = R_i \cap H \), for \( i = 1, 2. \) For a fixed \( i \) in \( \{ 1, 2 \} \), \( \text{Conv}(R_i) \) is contained in one of the half-spaces determined by \( H \) in \( E \), hence \( H \cap \text{Cone}(R_i) = \text{Cone}(R_i). \) Moreover, \( \text{Cone}(R_i) \) and \( \text{Cone}(R_2) \) belong to opposite half-spaces with respect to \( H \), hence, \( \text{Cone}(R_i) \cap \text{Cone}(R_2) = \text{Cone}(R_i) \cap \text{Cone}(R_2). \) Moreover, \( R_1 \cap R_2 = R_1 \cap R_2. \) Arguing by induction as in case (b1), we obtain \( \text{Cone}(R_1) \cap \text{Cone}(R_2) \subseteq \text{Cone}(R_1 \cap R_2) \), hence the claim. \( \square \)

Corollary 6.5 and Propositions 6.6 and 6.7 imply directly the following theorem, which is Theorem 1.1.

**Theorem 6.8.** Let \( F \) be a facet of \( P \), \( I_F \) be the corresponding facet ideal, and \[ T_{I_F} = \{ \text{Conv}(R) \mid R \in \mathcal{R}_{I_F}, \ rk(R) = n \}. \]

Then \( T_{I_F} \) is a triangulation of \( F \).

**Corollary 6.9.** Each maximal reduced subset in \( I \) is contained in a maximal reduced subset. Moreover, each maximal reduced subset in \( I \) is a linear basis of \( E \).

**Proof.** Let \( R_0 \) be a reduced subset in \( I \) such that \( \text{rk}(R_0) < n \). Let \( x = \sum_{\beta \in R_0} c_{\beta} \beta \) with \( c_{\beta} > 0 \) for all \( \beta \in R_0 \). By Corollary 6.5, there exists a reduced subset \( R \) in \( I \) such that \( \text{rk}(R) = n \). Then, by Proposition 6.6, \( x \in \text{Conv}(R) \). By assumption, for each proper subset \( R' \) of \( R_0 \), \( x \notin \text{Conv}(R') \), hence \( R_0 \cap R = R_0 \). It follows \( R_0 \subseteq R \). Thus, a maximal reduced subset in \( I \) has rank \( n \). By Proposition 6.6, it is also linearly independent, hence, it is a linear basis of \( E \). \( \square \)

We can finally prove the following result, which is equivalent to Theorem 1.2. The proof refers to the case by case analysis of Proposition 5.11.

**Theorem 6.10.** Let \( F \) be a facet of \( P \), \( I_F \) be the corresponding facet ideal, and \( R \) be a maximal reduced subset in \( I_F \). Then \( R \) is a \( \mathbb{Z} \)-basis of the sub-lattice of \( L(\Phi) \) generated by \( (\Pi \setminus \{ \alpha_F \}) \cup \{ m_{\alpha_F} \alpha_F \} \), where \( \alpha_F \) is the simple root such that \( F = F_{\alpha_F} \).

**Proof.** Let \( I = I_F \). By Proposition 3.2 and Remark 3.3, it suffices to prove the claim in case \( I \) is an abelian nilradical of \( \Phi^+ \), i.e. \( m_{\alpha_F} = 1 \). Thus we have \( \alpha_F = \alpha_I \) and \( I = (\alpha_I) \), as before. Under this assumption, we have to prove that \( R \) is a \( \mathbb{Z} \)-basis of \( L(\Phi). \)

Let \( \leq \) be a triangulation order of \( I \) and \( \beta = \min_{<} R \). If \( \beta \) is detachable in \( \langle \beta \rangle \), let \( J = (\beta \setminus \{ \beta \}) \setminus \{ \beta \}. \) If \( \beta \) is not detachable in \( \langle \beta \rangle \), let \( \{ J_i, J_i \} \) be a bipartition of \( \langle \beta \rangle \) such that \( \beta \) belongs to \( J_i \) and \( J_i \) is detachable in them. In this case, \( R \) is contained in exactly one of \( J_i \) and \( J_i \); we define \( J = J_i \) if \( R \subseteq J_i \), and \( J = J_i \) otherwise. In any case, let \( H \) be the separating hyperplane for \( \beta \) in \( J \). Then, \( \text{Red}(\beta) \cap J = H \cap J \), hence \( R \setminus \{ \beta \} \) is a reduced subset in the abelian nilradical \( I \cap H \) of \( (\Phi \cap H)^+ \). Since \( \text{rk}(R \setminus \{ \beta \}) = n - 1 \), also \( \text{rk}(I \cap H) = \text{rk}(\Phi \cap H) = n - 1 \). In particular \( I \cap H \) has nontrivial intersection with each irreducible component of \( \Phi \cap H \). By Lemma 3.4, each of these intersections is a nontrivial abelian nilradical in its irreducible component, hence, by induction on the dimension, \( R \setminus \{ \beta \} \) is a \( \mathbb{Z} \)-basis of \( L(\Phi \cap H). \)

Now, we first consider the case in which \( \beta \) is long and is equal to \( \min J \) or \( \max J \) with respect to standard partial order. In this case, as seen in the proof of Lemma 5.7, we may take \( H = (\beta' - \omega_{\alpha}) \). It follows directly that all simple roots different from \( \alpha_f \) and perpendicular to \( \beta \) belong to \( H \). For all other simple roots \( \alpha \neq \alpha_f \), either \( (\alpha, \beta') = 1 \) and \( \beta - \alpha \in H \), or \( (\alpha, \beta') = -1 \) and \( \beta + \alpha \in H \). By the induction assumption, we obtain that, for all \( \alpha \in \Pi \setminus \{ \alpha_f \} \), either \( \alpha \), or one of \( \beta \pm \alpha \), is an integral linear combination of \( R \setminus \{ \beta \} \). It follows that the \( \mathbb{Z} \)-span of \( R \) contains
(II \setminus \alpha_I). Since \beta \in R and c_{\alpha_I}(\beta) = 1, it follows that the \mathbb{Z}\text{-span of } R contains II, which yields the claim.

Looking at the proof of Proposition 5.11, we can check that also in the remaining cases we may take H so as to satisfy the following condition: for all \alpha \in II \setminus \{\alpha_I\}, either \alpha \in H, or one of \beta \pm \alpha \in H. Arguing as in the previous case, we obtain that R is a \mathbb{Z}\text{-basis of } L(\Phi). 

\section{Concluding remarks}

We may transfer a triangulation \mathcal{T}_F of a standard parabolic facet F to all facets in its orbit, by the action of the Weyl group W. If \varpi \in W and Stab(F) = \{w \in W \mid wF = F\}, then, for all v \in \varpi Stab(F) we have that v\mathcal{T}_F is a triangulation of \varpi F. Thus, a set of representatives of the left cosets in W/Stab(F) determines an extension of \mathcal{T}_F to the whole orbit WF. We can prove that, by a suitable choice of the coset representatives for all standard parabolic facets, we may obtain a triangulation of the whole boundary \partial P of the root polytope P. Let \mathcal{T} be a triangulation of \partial P obtained by extending, through the action of W, the triangulations of the standard parabolic facets provided in Section 6. If we set T_0 = Conv(T \cup \{0\}), for or each \mathcal{T} \in \mathcal{T}, then \mathcal{T}_0 := \{T_0 \mid \mathcal{T} \in \mathcal{T}\} is a triangulation of P. Theorem 6.10 allows to compute the volumes Vol(T_0), which are constant on each facet orbit. Thus, the explicit enumeration of the maximal reduced subsets of facet ideals, together with the results in [6] on face orbits, would allow to compute the volume of P. For the root types A and C, this is done in [4]. The proof of Proposition 5.11 gives an explicit procedure for enumerating the maximal reduced subsets, hence provides an effective way for making a similar computation for the remaining root types.

In [4] it is also proved that, for the root types A and C, the triangulation \mathcal{T}_0 of \mathcal{P} restricts to a triangulation of the positive root polytope \mathcal{P}^+ = Conv(\Phi^+ \cup \{0\}). In fact, this is a proof that, for these root types, the intersection of \mathcal{P} with the cone on \Phi^+ is equal to \mathcal{P}^+. This is one of the special properties of the root polytope that hold only for the types A and C (see also [5]). Indeed, it is easy to see that, for all other root types, \mathcal{P}^+ is properly contained in \mathcal{P} \cap Cone(\Phi^+) [10]. Hence, in these cases, from a triangulation of the standard parabolic facets, we cannot obtain a triangulation of the positive root polytope in a natural way.
