Noncommutative Bell polynomials and the dual immaculate basis

Jean-Christophe Novelli, Jean-Yves Thibon & Frédéric
 Toumazet

ABSTRACT We define a new family of noncommutative Bell polynomials in the algebra of free quasi-symmetric functions and relate it to the dual immaculate basis of quasi-symmetric functions. We obtain noncommutative versions of Grinberg’s results [14], and interpret these in terms of the tridendriform structure of **WQSym**. We then present a variant of Rey’s self-dual Hopf algebra of set partitions [35] adapted to our noncommutative Bell polynomials and give a complete description of the Bell equivalence classes as linear extensions of explicit posets.

1. INTRODUCTION

Many classical combinatorial numbers or polynomials are the dimensions (or graded dimensions) of certain representations of the symmetric groups, and can therefore be regarded as specializations of the symmetric functions encoding the characters of these representations [7]. Classical examples include the Euler numbers [10], or the Eulerian polynomials [11]. In both cases, the generating series of the relevant symmetric functions can be obtained as the homomorphic images of multiplicity-free series living in some (in general noncommutative) combinatorial Hopf algebra. For example, the generating series $\tan x + \sec x$ of the Euler numbers is the image of the formal sum of all alternating permutations in the Hopf algebra of free quasi-symmetric functions **FQSym** by its canonical character, and its lift by Foulkes to symmetric functions is just the commutative image of the same series [12, 19].

Other examples of this situation include the derangement numbers [15], the numbers of parking functions [29], the Abel polynomials [29] or Arnold’s snakes [19].

These combinatorial numbers can also be dimensions of representations of the 0-Hecke algebra, which cannot be lifted to the generic Hecke algebra or to the symmetric group. This is the case, for example, for linear extensions of a poset [8], which can be directly interpreted as free quasi-symmetric functions.

The aim of this paper is to apply this philosophy to the Bell polynomials. Their relation with symmetric functions is well-known, and easily extended to noncommutative symmetric functions. At this level, it is already possible to define a non-trivial q -analogue, which points toward the most promising direction for the next step. There is a natural choice of a representation of set partitions by permutations in **FQSym** which is compatible with this q -analogue. The Bell polynomials are then lifted to

Manuscript received 11th December 2017, revised 26th February 2018 and 12th June 2018, accepted 17th June 2018.

KEYWORDS. Noncommutative symmetric functions, Quasi-symmetric functions, Bell polynomials, Dendriform algebras.

polynomials in noncommuting variables Y_k , with coefficients in **FQSym**. One can then consider the quasi-symmetric functions C_I which are the commutative images of the coefficients of the monomials Y^I . It turns out that they coincide with the dual immaculate basis of [2], up to mirror image of compositions.

The formal sum of these “free Bell polynomials” satisfies a simple functional equation in terms of the dendriform structure of **FQSym**. This allows us to obtain expressions of the dual immaculate basis similar to (but different from) those of Grinberg [14]. Actually, Grinberg works directly at the level of quasi-symmetric functions, and his formula comes in fact from the tridendriform structure of **WQSym**.

Finally, we discuss briefly the connection with the self-dual Hopf algebra of set partitions introduced by Rey in [35].

2. BELL POLYNOMIALS AND NONCOMMUTATIVE SYMMETRIC FUNCTIONS

2.1. BELL POLYNOMIALS AND SYMMETRIC FUNCTIONS. The classical Bell (exponential) polynomials are defined by

$$(1) \quad B_0 = 1, \quad B_{n+1}(y_1, \dots, y_{n+1}) = \sum_{k=0}^n \binom{n}{k} B_{n-k} y_{k+1}$$

or equivalently by the exponential generating series

$$(2) \quad \mathcal{B}(t) := \sum_{n \geq 0} B_n \frac{t^n}{n!} = \exp \left(\sum_{k \geq 1} y_k \frac{t^k}{k!} \right).$$

This is reminiscent of the relation between power-sums and complete symmetric functions [24]. The power sums are

$$(3) \quad p_n = \sum_{i \geq 1} x_i^n$$

and the complete symmetric function h_n is the sum of all monomials of degree n , with generating series

$$(4) \quad H(t) = \sum_{n \geq 0} h_n t^n = \prod_{i \geq 1} \frac{1}{1 - tx_i} = \exp \left(\sum_{k \geq 1} p_k \frac{t^k}{k} \right)$$

so that if one sets $y_n = (n-1)!p_n$, then $B_n = n!h_n$, and for $y_n = (-1)^{n-1}(n-1)!p_n$, B_n becomes $n!e_n$, where the e_n are the elementary symmetric functions.

2.2. NONCOMMUTATIVE BELL POLYNOMIALS. This is easily extended to noncommutative symmetric functions. Recall [12] that the algebra **Sym** of noncommutative symmetric functions is freely generated⁽¹⁾ by noncommuting indeterminates S_n playing the role of the h_n . The noncommutative analogues of the p_n are not canonically determined, and one possibility is to define noncommutative power-sums of the first kind Ψ_n by orienting the Newton recursion as [12, Prop. 3.3]

$$(5) \quad (n+1)S_{n+1} = \sum_{k=0}^n S_{n-k} \Psi_{k+1}.$$

These power-sums correspond to the Dynkin elements in the descent algebras [12].

⁽¹⁾All our algebras are taken over some unspecified field $\mathbb{K}$ of characteristic 0, assumed to contain all indeterminates and formal power series implied by the context.

Let $(Y_n)_{n \geq 1}$ be a sequence of noncommuting indeterminates. For a composition $I = (i_1, \dots, i_r)$, let $Y^I = Y_{i_1} \cdots Y_{i_r}$. The recurrence (1) can be similarly oriented as

$$(6) \quad B'_{n+1} = \sum_{k=0}^n \binom{n}{k} B'_{n-k} Y_{k+1} \text{ or } B''_{n+1} = \sum_{k=0}^n \binom{n}{k} Y_{k+1} B''_{n-k}.$$

Then, $B'_n = n!S_n$ for $Y_n = (n-1)!\Psi_n$ and $B''_n = n!S_n$ for $Y_n = (n-1)!\bar{\Psi}_n$ (where the $\bar{\Psi}_n$ are defined by the opposite Newton recursion

$$(7) \quad (n+1)S_{n+1} = \sum_{k=0}^n \bar{\Psi}_{k+1} S_{n-k},$$

and correspond to the right-sided Dynkin elements). Such noncommutative Bell polynomials have been discussed in [36] (see also [31, 9]).

It is enough to describe one version, since the antiautomorphism $Y_i \mapsto Y_i$ exchanges B'_n and B''_n . Let us choose the second one. For now on, we set $B = B''$.

The first values are

$$(8) \quad \begin{aligned} B_1 &= Y^1 \\ B_2 &= Y^2 + Y^{11} \\ B_3 &= Y^3 + 2Y^{21} + Y^{12} + Y^{111} \\ B_4 &= Y^4 + 3Y^{31} + 3Y^{22} + 3Y^{211} + Y^{13} + 2Y^{121} + Y^{112} + Y^{1111} \\ B_5 &= Y^5 + 4Y^{41} + 6Y^{32} + 6Y^{311} + 4Y^{23} + 8Y^{221} + 4Y^{212} + 4Y^{2111} \\ &\quad + Y^{14} + 3Y^{131} + 3Y^{122} + 3Y^{1211} + Y^{113} + 2Y^{1121} + Y^{1112} + Y^{11111} \end{aligned}$$

The coefficients have a simple combinatorial interpretation in terms of set partitions. We shall represent a set partition either by a set of sets or by any sequence of its parts separated by a vertical bar. For example, $\pi = \{\{3, 4, 7\}, \{2, 8\}, \{1\}, \{5, 6\}\}$ will also be represented as 347|28|1|56.

For a set partition π of $[n]$, let $\pi^\sharp$ be the set composition obtained by ordering the blocks of π w.r.t. their minima, and let $K(\pi)$ be the composition recording the sizes of the blocks of $\pi^\sharp$. For example, if $\pi = 347|28|1|56$, then $\pi^\sharp = 1|28|347|56$, and $K(\pi) = (1, 2, 3, 2)$. Then, the coefficient of Y^I in B_n is the number of set partitions π of $[n]$ such that $K(\pi) = I$ (this follows by induction on n , as the first block of $\pi^\sharp$ is always the one containing 1). For example, the coefficient of Y^{23} in B_5 enumerates the set of partitions

$$(9) \quad 12|345, 13|245, 14|235, 15|234,$$

whereas the coefficient of Y^{32} in B_5 enumerates

$$(10) \quad 123|45, 124|35, 125|34, 134|25, 135|24, 145|23.$$

2.3. q -ANALOGUES. In [20, §5.1], a noncommutative analogue of the classical transformation $p_n \mapsto (1 - q^n)p_n$ of ordinary symmetric functions has been defined as the algebra automorphism

$$(11) \quad \alpha_q : S_n(A) \mapsto S_n((1 - q)A) = (1 - q) \sum_{k=0}^{n-1} (-q)^k R_{1^k, n-k}$$

(where the R_I are the noncommutative ribbon Schur functions), which is the inverse of ([20, §6.1])

$$(12) \quad \beta_q : S_n(A) \mapsto S_n\left(\frac{A}{1 - q}\right)$$

where $\frac{A}{1-q}$ denotes the (genuine) alphabet $\{q^i a_j\}$ endowed with the order $q^i a_j < q^k a_l$ iff $i > k$ or $i = k$ and $j < l$.

In terms of the generating series of complete and elementary functions

$$(13) \quad \sigma_t(A) := \sum_{n \geq 0} t^n S_n(A) = \prod_{i \geq 1} (1 - t a_i)^{-1}, \quad \lambda_{-t}(A) = \sum_{n \geq 0} (-t)^n \Lambda_n(A) = \sigma_t(A)^{-1},$$

these transformations read

$$(14) \quad \sigma_t \left(\frac{A}{1-q} \right) = \prod_{k \geq 0}^{\leftarrow} \sigma_{q^k t}(A) = \cdots \sigma_{q^2 t}(A) \sigma_{q t}(A) \sigma_t(A)$$

and

$$(15) \quad \sigma_t((1-q)A) = \lambda_{-qt}(A) \sigma_t(A).$$

It follows from (11) that the Dynkin power-sums Ψ_n are limiting cases of the transformed complete functions (see [20] for an explanation of the notation)

$$(16) \quad \Psi_n = \lim_{q \rightarrow 1} \frac{S_n((1-q)A)}{1-q}$$

and similarly

$$(17) \quad (-1)^{n-1} \Psi_n = \lim_{q \rightarrow 1} \frac{\Lambda_n((1-q)A)}{1-q}.$$

Indeed, it is known that $\Psi_n = \sum_{k=0}^{n-1} (-1)^k R_{1^k, n-k}$, and

$$(18) \quad \sum_{n \geq 0} (-t)^n \Lambda_n((1-q)A) = \sigma_t((1-q)A)^{-1} = (\lambda_{-qt}(A) \sigma_t(A))^{-1}$$

$$(19) \quad = \lambda_{-t}(A) \sigma_{qt}(A) = \sigma_1((q-1)tA) = \sigma_{qt} \left(\left(1 - \frac{1}{q}\right) A \right)$$

so that

$$(20) \quad \Lambda_n((1-q)A) = (-1)^n (q-1) \sum_{k=0}^{n-1} \left(-\frac{1}{q} \right)^{n-1-k} R_{1^k, n-k}.$$

Replacing A by $A/(1-q)$, one can define q -analogues of B'_n and B''_n by

$$(21) \quad B'_n(q) = (q)_n S_n \left(\frac{A}{1-q} \right) \text{ for } Y_n = (q)_{n-1} S_n(A)$$

and

$$(22) \quad B''_n(q) = (q)_n \Lambda_n \left(\frac{A}{1-q} \right) \text{ for } Y_n = (q)_{n-1} \Lambda_n(A),$$

where $(q)_n := \prod_{i=1}^n (1 - q^i)$.

This amounts to defining $B'_n(q)$ by the recursion

$$(23) \quad B'_n(q) = \sum_{k=0}^{n-1} q^k \begin{bmatrix} n-1 \\ k \end{bmatrix}_q B'_k(q) Y_{n-k} \quad (\text{and } B_0 = 1).$$

Indeed,

$$(24) \quad B'_n(q) = (q)_n S_n((\cdots + q^2 A + qA) + A)$$

$$(25) \quad = (q)_n S_n\left(\frac{qA}{1-q} + A\right)$$

$$(26) \quad = (q)_n \sum_{k=0}^n S_k\left(\frac{qA}{1-q}\right) S_{n-k}(A)$$

$$(27) \quad = (q)_n \sum_{k=0}^n q^k S_k\left(\frac{A}{1-q}\right) S_{n-k}(A)$$

$$(28) \quad = \sum_{k=0}^{n-1} \frac{(q)_n}{(q)_k} q^k B'_k(q) \frac{Y_{n-k}}{(q)_{n-k-1}} + (q)_n q^n S_n\left(\frac{A}{1-q}\right)$$

$$(29) \quad = (1 - q^n) \sum_{k=0}^{n-1} \left[\begin{matrix} n-1 \\ k \end{matrix} \right]_q q^k B'_k(q) Y_{n-k} + q^n B'_n(q).$$

The same argument yields for $B''_n(q)$

$$(30) \quad B''_n(q) = \sum_{k=0}^{n-1} q^k Y_{n-k} \left[\begin{matrix} n-1 \\ k \end{matrix} \right]_q B''_k(q) \quad (\text{and } B_0 = 1).$$

The first values are

$$(31) \quad \begin{aligned} B'_1 &= Y^1 \\ B'_2 &= Y^2 + qY^{11} \\ B'_3 &= Y^3 + q^2Y^{21} + (q^2 + q)Y^{12} + q^3Y^{111} \\ B'_4 &= Y^4 + q^3Y^{31} + (q^4 + q^3 + q^2)Y^{22} + q^5Y^{211} \\ &\quad + (q^3 + q^2 + q)Y^{13} + (q^5 + q^4)Y^{121} + (q^5 + q^4 + q^3)Y^{112} + q^6Y^{1111} \end{aligned}$$

and

$$(32) \quad \begin{aligned} B''_1 &= Y^1 \\ B''_2 &= Y^2 + qY^{11} \\ B''_3 &= Y^3 + (q^2 + q)Y^{21} + q^2Y^{12} + q^3Y^{111} \\ B''_4 &= Y^4 + (q^3 + q^2 + q)Y^{31} + (q^4 + q^3 + q^2)Y^{22} + (q^5 + q^4 + q^3)Y^{211} \\ &\quad + q^3Y^{13} + (q^5 + q^4)Y^{121} + q^5Y^{112} + q^6Y^{1111}. \end{aligned}$$

Setting $Y_i = 1$ in B'_n or in B''_n , one obtains the triangle A188919 of [37]:

$$(33) \quad \begin{aligned} b_1(q) &= 1 \\ b_2(q) &= 1 + q \\ b_3(q) &= 1 + q + 2q^2 + q^3 \\ b_4(q) &= 1 + q + 2q^2 + 4q^3 + 3q^4 + 3q^5 + q^6 \\ b_5(q) &= 1 + q + 2q^2 + 4q^3 + 7q^4 + 8q^5 + 9q^6 + 9q^7 + 6q^8 + 4q^9 + q^{10}. \end{aligned}$$

The On-Line Encyclopedia of Integer Sequences [37] suggests that the coefficient of q^k in $b_n(q)$ should be the number of permutations of length n with k inversions that avoid the dashed pattern $1 - 32$ [1]. The proof of this fact will follow from a refined

interpretation for the coefficient of Y^I in $B'_n(q)$ (Proposition 3.4 below). Indeed, it follows from (23) that this coefficient is⁽²⁾

$$(34) \quad \prod_{k=2}^{\ell(I)} \begin{bmatrix} i_1 + \cdots + i_k - 1 \\ i_k - 1 \end{bmatrix}_q q^{i_1 + \cdots + i_{k-1}}.$$

This suggests that the counting of $1 - 32$ -avoiding permutations can be refined according to their descent sets. To do this, we have to replace the binomial coefficients in the recurrence by formal sums of permutations in an appropriate algebra.

As we have seen, the Bell polynomials are essentially the expressions of the complete homogeneous symmetric functions on suitably normalized power sums. This expression is classically given by a determinant, which has been lifted to the non-commutative case in [9, Thm. 2.5] as a quasideterminant. Expressions of the S_n as quasideterminants in the Ψ_n have been given in [12], and have been extended to the q -analogues $\Theta_n(q) = (1 - q)^{-1} S_n((1 - q)A)$ of the Ψ_n in [20, Prop. 5.5]. A straightforward manipulation of this quasideterminant yields the following q -analogue of [9, Thm. 2.5]:

PROPOSITION 2.1. $B'_n(q)$ is given by the quasideterminant

$$(35) \quad B'_n(q) = |\mathbb{B}'_n|_{1n}$$

where $\mathbb{B}'_n$ is the $n \times n$ matrix whose subdiagonal elements are -1 , the lower elements are all zero, and the elements on and above the diagonal are

$$(36) \quad (\mathbb{B}'_n)_{ij} = q^{i-1} \begin{bmatrix} n - (n - j + 1) \\ j - i \end{bmatrix}_q Y_{j-i+1} \text{ (for } i \leq j \text{)}.$$

Proof. Recall that the q -factorial is defined by $[n]_q! = [n]_q [n-1]_q \cdots [1]_q$, where $[n]_q = (1 - q^n)/(1 - q)$. Applying the inverse transformation β_q , it is clear that $B'_n(q)$ is also the polynomial expressing $[n]_q! S_n(A)$ in terms of the $Y_k = [k-1]_q! \Theta_k(q)$ (which are obviously a set of free generators of **Sym** on $\mathbb{K}(q)$). Indeed, setting

$$(37) \quad B'_n(q) = \sum_{I \models n} c_I(q) Y^I = \sum_{I \models n} c_I(q) \prod_{k=1}^{\ell(I)} (q)_{i_k-1} S_{i_k}(A)$$

we have

$$(38) \quad (q)_n S_n(A) = \sum_{I \models n} c_I(q) \prod_{k=1}^{\ell(I)} (q)_{i_k-1} S_{i_k}((1 - q)A)$$

$$(39) \quad = \sum_{I \models n} c_I(q) \prod_{k=1}^{\ell(I)} (q)_{i_k-1} (1 - q)^{\ell(I)} \cdot \Theta^I(q)$$

and dividing by $(1 - q)^n$ yields

$$(40) \quad [n]_q! S_n(A) = \sum_{I \models n} c_I(q) \prod_{k=1}^{\ell(I)} [i_k - 1]_q! (1 - q)^{i_k-1} \cdot (1 - q)^{\ell(I)} \Theta^I(q)$$

$$(41) \quad = \sum_{I \models n} c_I(q) \prod_{k=1}^{\ell(I)} [i_k - 1]_q! \cdot \Theta^I(q).$$

⁽²⁾This is a q -analogue of the r.h.s. of [31, (78)].

In the quasideterminant (78) of [20], expressing $S_n(A)$ in terms of $\Theta_n(q)$

$$(42) \quad [n]_q S_n(A) = \begin{vmatrix} \Theta_1(q) & \Theta_2(q) & \dots & \Theta_{n-1}(q) & \boxed{\Theta_n(q)} \\ -[1]_q & q\Theta_1(q) & \dots & q\Theta_{n-2}(q) & q\Theta_{n-1}(q) \\ 0 & -[2]_q & \dots & q^2\Theta_{n-3}(q) & q^2\Theta_{n-2}(q) \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & 0 & \dots & -[n-1]_q & q^{n-1}\Theta_1(q) \end{vmatrix}.$$

multiply column j by $[j-1]_q!$ and divide row i by $[i-1]_q!$. These operations do not change the value of the quasideterminant, except for the last column, which yields a factor $[n-1]_q!$, so that the l.h.s. of [20, (78)] is now $[n]_q! S_n$. Replacing each entry $\Theta_k(q)$ by $\frac{1}{[k-1]_q!} Y_k$ yields the desired expression. $\square$

For example,

$$(43) \quad B'_4(q) = \begin{vmatrix} Y_1 & Y_2 & Y_3 & \boxed{Y_4} \\ -1 & q \begin{bmatrix} 2 \\ 0 \end{bmatrix}_q Y_1 & q \begin{bmatrix} 2 \\ 1 \end{bmatrix}_q Y_2 & q \begin{bmatrix} 2 \\ 2 \end{bmatrix}_q Y_3 \\ 0 & -1 & q^2 \begin{bmatrix} 3 \\ 0 \end{bmatrix}_q Y_1 & q^2 \begin{bmatrix} 3 \\ 1 \end{bmatrix}_q Y_2 \\ 0 & 0 & -1 & q^3 \begin{bmatrix} 4 \\ 0 \end{bmatrix}_q Y_1 \end{vmatrix}.$$

Note that Equation (77) of [20] allows one to express Y_n in terms of the B_k , as in [9, §3.2.6].

3. QUASI-SYMMETRIC ANALOGUES OF THE COEFFICIENTS

3.1. FREE QUASI-SYMMETRIC FUNCTIONS AND THEIR DENDRIFORM STRUCTURE. Recall that for a totally ordered alphabet A , $\mathbf{FQSym}(A)$ is the algebra spanned by the noncommutative power series [8]

$$(44) \quad \mathbf{G}_\sigma(A) := \sum_{\substack{w \in A^n \\ \text{Std}(w) = \sigma}} w$$

where σ is a permutation in the symmetric group $\mathfrak{S}_n$ and $\text{Std}(w)$ denotes the standardization of the word w , i.e., the unique permutation having the same inversions as w .

All countably infinite alphabets lead to isomorphic algebras. In the sequel, we fix one such alphabet A and denote the resulting algebra $\mathbf{FQSym}(A)$ simply by $\mathbf{FQSym}$.

The multiplication rule is the same as in the Malvenuto–Reutenauer algebra [25], to which $\mathbf{FQSym}$ is therefore isomorphic⁽³⁾

$$(45) \quad \mathbf{G}_\alpha \mathbf{G}_\beta = \sum_{\gamma \in \alpha * \beta} \mathbf{G}_\gamma,$$

where the convolution $\alpha * \beta$ of $\alpha \in \mathfrak{S}_k$ and $\beta \in \mathfrak{S}_l$ is defined as the sum in the group algebra of $\mathfrak{S}_{k+l}$ in [25]

$$(46) \quad \alpha * \beta = \sum_{\substack{\gamma = uv \\ \text{Std}(u) = \alpha; \text{Std}(v) = \beta}} \gamma.$$

Permutations are here interpreted as words, and uv means concatenation. The result is interpreted here as a set. Indeed, there are no multiplicities in this sum, and the

⁽³⁾The interest of this isomorphism resides in the fact that the Hopf algebra structure is then induced by the ordered sum of alphabets, as for noncommutative symmetric functions.

number of terms in $\mathbf{G}_\alpha \mathbf{G}_\beta$ is $\binom{k+l}{k}$. To reduce this number to $\binom{k+l-1}{k}$ and relate to the Bell induction concerning B_n'' , we can split the product according to the dendriform structure of **FQSym**.

The dendriform structure of **FQSym**, originally defined in [23], can be seen as inherited from the tridendriform structure of the algebra of noncommutative formal power series over A defined in [26, 27]. Define bilinear operators on nonempty words u, v by

$$(47) \quad u \prec v = \begin{cases} uv & \text{if } \max(v) < \max(u) \\ 0 & \text{otherwise,} \end{cases}$$

$$(48) \quad u \succ v = \begin{cases} uv & \text{if } \max(v) \geq \max(u) \\ 0 & \text{otherwise.} \end{cases}$$

Note that the operator $\succ$ here is $\succ + \circ$ of [26, 27]. Also, our conventions differ from those of Grinberg [14, Def. 6.1] who uses $\min$ instead of $\max$, and $>$ and $<$ instead of $<$ and $\geq$. This yields

$$(49) \quad \mathbf{G}_\alpha \mathbf{G}_\beta = \mathbf{G}_\alpha \prec \mathbf{G}_\beta + \mathbf{G}_\alpha \succ \mathbf{G}_\beta,$$

where

$$(50) \quad \mathbf{G}_\alpha \prec \mathbf{G}_\beta = \sum_{\substack{\gamma = uv \in \alpha * \beta \\ |u| = |\alpha|; \max(v) < \max(u)}} \mathbf{G}_\gamma,$$

$$(51) \quad \mathbf{G}_\alpha \succ \mathbf{G}_\beta = \sum_{\substack{\gamma = uv \in \alpha * \beta \\ |u| = |\alpha|; \max(v) \geq \max(u)}} \mathbf{G}_\gamma.$$

Then $x = \mathbf{G}_1$ generates a free dendriform algebra in **FQSym**, isomorphic to **PBT**, the Loday–Ronco algebra of planar binary trees [22, Prop. 3.7] and [23, Prop. 5.3]. The notations used here are those of [16], where more details can be found.

Recall that the shuffle product $\sqcup$ is recursively defined by

$$(52) \quad ua \sqcup vb = (ua \sqcup v)b + (u \sqcup vb)a,$$

where a, b are letters and u, v words. The scalar 1 (representing the empty word) is the neutral element. The shuffle can be split into two half-products $\prec$ and $\succ$ defined by

$$(53) \quad ua \prec vb = (u \sqcup vb)a, \quad ua \succ vb = (ua \sqcup v)b,$$

We shall not need dendriform products involving 1 and thus leave these undefined.

In terms of the dual basis $\mathbf{F}_\sigma := \mathbf{G}_{\sigma^{-1}}$,

$$(54) \quad \mathbf{F}_\alpha \mathbf{F}_\beta = \sum_{\gamma \in \alpha \sqcup \beta[k]} \mathbf{F}_\gamma,$$

$$(55) \quad \mathbf{F}_\alpha \prec \mathbf{F}_\beta = \sum_{\gamma \in \alpha \prec \beta[k]} \mathbf{F}_\gamma,$$

$$(56) \quad \mathbf{F}_\alpha \succ \mathbf{F}_\beta = \sum_{\gamma \in \alpha \succ \beta[k]} \mathbf{F}_\gamma,$$

where $\alpha \in \mathfrak{S}_k$, $\beta[k]$ denotes β with its entries shifted by k .

There is an inclusion of Hopf algebras $\mathbf{Sym} \hookrightarrow \mathbf{PBT}$ of noncommutative symmetric functions into **PBT** [22, 23], which is given by

$$(57) \quad S_n = (\dots((x \succ x) \succ x) \dots) \succ x \quad (n \text{ times}).$$

Indeed, the r.h.s is the sum of nondecreasing words, i.e., $\mathbf{G}_{1\dots n} = S_n$.

3.2. A DENDRIFORM LIFT OF THE BELL RECURRENCE. We shall define the free Bell polynomials as elements of $\mathbb{K}\langle Y_1, Y_2, \dots \rangle \otimes \mathbf{FQSym}$ by

$$(58) \quad B_0 = 1, \quad B_{n+1} = \sum_{k=0}^n Y_{k+1} S_{k+1} \prec B_{n-k},$$

the $\otimes$ sign being omitted for notational convenience, and $\prec$ is actually $\cdot \otimes \prec$. Recall also that $S_{k+1} = \mathbf{G}_{1\dots k+1}$. The first B_n are

$$(59) \quad \begin{aligned} B_0 &= 1 \\ B_1 &= Y^1 \mathbf{G}_1 \\ B_2 &= Y^2 \mathbf{G}_{12} + Y^{11} \mathbf{G}_{21} \\ B_3 &= Y^3 \mathbf{G}_{123} + Y^{21} (\mathbf{G}_{132} + \mathbf{G}_{231}) + Y^{12} \mathbf{G}_{312} + Y^{111} \mathbf{G}_{321} \\ B_4 &= Y^4 \mathbf{G}_{1234} + Y^{31} (\mathbf{G}_{1243} + \mathbf{G}_{1342} + \mathbf{G}_{2341}) \\ &\quad + Y^{22} (\mathbf{G}_{1423} + \mathbf{G}_{2413} + \mathbf{G}_{3412}) + Y^{211} (\mathbf{G}_{1432} + \mathbf{G}_{2431} + \mathbf{G}_{3421}) \\ &\quad + Y^{13} \mathbf{G}_{4123} + Y^{121} (\mathbf{G}_{4132} + \mathbf{G}_{4231}) + Y^{112} \mathbf{G}_{4312} + Y^{1111} \mathbf{G}_{4321}. \end{aligned}$$

Clearly, for each $n \geq 0$, B_n is a (left) $\mathbf{FQSym}$ -linear combination of the Y^I for various compositions I of n . The coefficient $C_I(A)$ of Y^I in B_n is by definition in $\mathbf{FQSym}$ but is in fact in $\mathbf{PBT}$:

LEMMA 3.1. *Let $I = (i_1, \dots, i_r)$ be a composition. Then $C_I(A)$ is equal to $\mathbf{P}_T$ where T is the right-comb tree whose left branches have sizes from top to bottom equal to $i_1, i_2, \dots, i_r$.*

Proof. The coefficient $C_I(A)$ is by definition equal to

$$(60) \quad S_{i_1} \prec (S_{i_2} \prec (\dots (S_{i_{r-1}} \prec S_{i_r}) \dots)).$$

Let n be $i_1 + \dots + i_r$ and expand that product in $\mathbf{FQSym}$ on the $\mathbf{G}$ basis. Consider any permutation τ such that $\mathbf{G}_\tau$ occurs in the expansion. By definition of $\prec$, the first i_1 letters of τ are increasing and the i_1 -th letter is n , then followed by a word whose standardization σ belongs to $S_{i_2} \prec (\dots (S_{i_{r-1}} \prec S_{i_r}) \dots)$. Hence, by induction on r , the decreasing tree (see [22, 16]) of all these elements is obtained by grafting the shape of the decreasing tree of σ to the right of the root of a left branch of size i_1 . Conversely, since any permutation of decreasing tree T belongs to the left product (60), this product is equal to $\mathbf{P}_T$. $\square$

EXAMPLE 3.2. The coefficient of Y^{221} in B_5 is

$$\begin{aligned} \mathbf{G}_{12} \prec (\mathbf{G}_{132} + \mathbf{G}_{231}) &= \mathbf{G}_{15243} + \mathbf{G}_{25143} + \mathbf{G}_{35142} + \mathbf{G}_{45132} \\ &\quad + \mathbf{G}_{15342} + \mathbf{G}_{25341} + \mathbf{G}_{35241} + \mathbf{G}_{45231} \\ &= \mathbf{P} \end{aligned}$$

For a set partition π of $[n]$, let π^b be the set composition obtained by ordering the blocks w.r.t. their maximal values in decreasing order, and let $K(\pi)$ be the composition recording the lengths of these blocks. Let also $\hat{\pi}^b$ be the permutation obtained by reading the blocks in this order, where each block is read from the smallest to the largest element.

EXAMPLE 3.3. If $\pi = 347|28|1|56$, we have $\pi^b = 28|347|56|1$, so that $\hat{\pi}^b = 28347561$, and $K(\pi) = (2, 3, 2, 1)$.

PROPOSITION 3.4. *The coefficient of Y^I in B_n is the sum of all $\mathbf{G}_{\hat{\pi}^b}$ where π ranges over set partitions such that $K(\pi) = I$:*

$$(61) \quad B_n = \sum_{\pi \vdash [n]} Y^{K(\pi)} \mathbf{G}_{\hat{\pi}^b}.$$

Proof. This follows from the product rule (50). Indeed, as we have already seen, this coefficient is $S_{i_1} \prec (S_{i_2} \prec (\cdots (S_{i_{r-1}} \prec S_{i_r})) \cdots)$, which is the sum of $\mathbf{G}_{\sigma}$ over all permutations of the form $\sigma = u_1 u_2 \cdots u_r$, where each u_j is an increasing word of length i_j whose last letter is greater than all letters to its right. But these permutations are precisely the $\hat{\pi}^b$ for the set partitions π such that $K(\pi) = I$. $\square$

These permutations $\hat{\pi}^b$ are not those avoiding the pattern $1 - 32$ as above, but those avoiding the pattern $21 - 3$. As observed in [6, Prop. 1], there is a statistic-preserving bijection between both classes (in this case, the Schützenberger involution, which preserves the inversion number). Since the inverse major index and the inversion number are equidistributed on the set of permutations having a decreasing tree of a given shape [18, Thm. 2.7], the generating polynomial of inv on $1 - 32$ or of imaj on $21 - 3$ -avoiding permutations with descent composition I is

$$(62) \quad c_I(q) = C_I \left(\frac{1}{1-q} \right)$$

where the alphabet $\frac{1}{1-q}$ (the principal specialization of **FQSym**) is defined by

$$(63) \quad A \mapsto \{q^n | n \geq 0\} \text{ ordered by } q^i < q^j \text{ iff } i > j.$$

Indeed,

$$(64) \quad C_I \left(\frac{1}{1-q} \right) = \sum_{K(\pi)=I} \mathbf{G}_{\hat{\pi}^b} \left(\frac{1}{1-q} \right),$$

and

$$(65) \quad \mathbf{G}_{\sigma} \left(\frac{1}{1-q} \right) = F_I \left(\frac{1}{1-q} \right)$$

where I is the descent composition of σ^{-1} . It is well-known (see [13, Lem. 5.2] or [12, Prop. 5.10]) the specializations of the fundamental quasi-symmetric functions are

$$(66) \quad F_I \left(\frac{1}{1-q} \right) = \frac{q^{\text{maj}(I)}}{(q)_n}.$$

where $\text{maj}(I) = \text{maj}(\tau)$ for any permutation τ of shape I . Thus, specializing the **FQSym** coefficients in B_n , we obtain

$$(67) \quad (q)_n B_n \left(\frac{1}{1-q} \right) = B_n''(q),$$

since by definition, the recurrence (58) is a lift of (30).

Now that we understand that $c_I(q)$ is the principal specialization of a quasi-symmetric function, we can replace it by the commutative image $C_I(X)$ of $C_I(A)$ in $QSym$. Recall that if the letters a_i of our underlying alphabet A are replaced by commuting variables x_i , then $\mathbf{F}_{\sigma}$ becomes the fundamental quasi-symmetric function $F_I(X)$ where I is the descent composition of σ .

EXAMPLE 3.5. Recording the recoil compositions of the permutations occurring in C_{221} , we find

$$(68) \quad C_{221}(X) = F_{1121} + F_{1211} + F_{122} + F_{131} + F_{212} + 2F_{221} + F_{311}.$$

This may be compared with the dual immaculate basis of [2]:

$$(69) \quad \mathfrak{S}_{221}^* = F_{1121} + F_{113} + F_{1211} + 2F_{122} + F_{131} + F_{212} + F_{221}.$$

THEOREM 3.6. *Define the bar involution on $QSym$ by $\overline{F_I} = F_{\bar{I}}$, where for $I = (i_1, \dots, i_r)$, $\bar{I} = (i_r, \dots, i_1)$ denotes the mirror composition. Then, the dual immaculate basis is given by*

$$(70) \quad \mathfrak{S}_I^* = \overline{C_I(X)}.$$

Proof. According to [2, Prop. 3.37],

$$(71) \quad \mathfrak{S}_I^* = \sum_T F_{D(T)}$$

where the sum runs over all standard immaculate tableaux of shape I , and $D(T)$ denotes the descent composition of T as defined in [2]. This should not be confused with the usual descent composition of a permutation σ , which will be denoted by $C(\sigma)$.

A standard immaculate tableau T of shape I is a planar representation of a set partition $\pi = (\pi_1, \dots, \pi_r)$, whose blocks have been ordered in such a way that $\min(\pi_1) < \min(\pi_2) < \dots < \min(\pi_r)$, and such that $|\pi_j| = i_j$.

For example, the standard immaculate tableaux of shape $I = (2, 2, 1)$ are

$$(72) \quad \begin{array}{|c|c|} \hline 1 & 5 \\ \hline 2 & 4 \\ \hline 3 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 5 \\ \hline 2 & 3 \\ \hline 4 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 4 \\ \hline 2 & 5 \\ \hline 3 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 4 \\ \hline 2 & 3 \\ \hline 5 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 2 & 5 \\ \hline 4 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 3 \\ \hline 2 & 4 \\ \hline 5 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 3 & 5 \\ \hline 4 & \\ \hline \end{array} \quad \begin{array}{|c|c|} \hline 1 & 2 \\ \hline 3 & 4 \\ \hline 5 & \\ \hline \end{array}$$

The descent composition $D(T)$ encodes the set $\{i | i+1 \text{ is in a lower row}\}$, which is therefore the recoil set of the permutation $\hat{T}$ obtained by reading the rows of T from bottom to top and from left to right.

The descent compositions $D(T)$ of the above tableaux are

$$(73) \quad 113, 122, 1121, 131, 122, 1211, 212, 221.$$

These are the recoil compositions of the permutations $\hat{T}$

$$(74) \quad 32415, 42315, 32514, 52314, 42513, 52413, 43512, 53412,$$

whose descent compositions are obviously always $\bar{I} = (1, 2, 2)$.

The Schützenberger involution ν sends a permutation $\sigma \in \mathfrak{S}_n$ to the permutation $\sigma' = \nu(\sigma)$ obtained by replacing each entry i of σ by $n+1-i$ and then reading the resulting word from right to left. In other words, $\sigma' = \omega\sigma\omega$, where $\omega = n n-1 \dots 21$.

The effect of ν on descent compositions is the mirror image $C(\sigma') = \overline{C(\sigma)}$. Thus, for any standard immaculate tableau T of shape I and descent composition J , applying ν to the permutation $\sigma = \nu(\hat{T})$ yields

$$(75) \quad C(\sigma) = C(\nu(\hat{T})) = \overline{C(\hat{T})} = \bar{I} = I$$

while

$$(76) \quad C(\sigma^{-1}) = \overline{D(\hat{T})} = \bar{J}.$$

Moreover, ν exchanges the maxima and the minima, so that the rows of the ribbon diagram of σ form the blocks of a set partition $\pi = (\pi_1, \dots, \pi_r)$ ordered in such a way that $\max(\pi_1) > \max(\pi_2) > \dots > \max(\pi_r)$, and $|\pi_j| = i_j$. That is, $\sigma = \hat{\pi}^b$ for a set partition such that $K(\pi) = I$. Therefore,

$$(77) \quad \mathfrak{S}_I^* = \sum_{K(\pi)=I} \overline{F_{K(\hat{\pi}^b)}} = \overline{C_I(X)}.$$

On our running example, the permutations $\nu(\hat{T})$ are

$$(78) \quad 15243, 15342, 25143, 25341, 35142, 35241, 45132, 45231.$$

Their recoil compositions are, in order

$$(79) \quad 311, 221, 1211, 131, 221, 1121, 212, 122. \quad \square$$

NOTE 3.7. Theorem 3.6 provides an expression of the dual immaculate basis very similar to the one obtained by Grinberg [14]. However, our dendriform operations are different. The relations between both constructions will be clarified in the forthcoming section.

COROLLARY 3.8. *The $C_I(X)$ form a basis of $QSym$, so that the $\mathbf{P}_T$ indexed by right combs form a section of the projection $\mathbf{PBT} \rightarrow QSym$.*

COROLLARY 3.9. *$c_I(q)$ is given by the Björner–Wachs q -hook-length formula [4]: the inversion polynomial of the set of permutations having a decreasing tree of shape T is given by the same hook length formula as for the inverse major index, which is*

$$(80) \quad \sum_{T(\sigma)=T} q^{l(\sigma)} = [n]_q! \prod_{v \in T} \frac{q^{\delta_v}}{[h_v]_q},$$

where v runs over the vertices of T , h_v is the number of vertices of the subtree with root v , and δ_v is the number of vertices in the right subtree of v .

See [18] for a short proof of the version used here.

EXAMPLE 3.10. For $I = 221$, the hook-lengths h_v of the right comb are 5, 3, 1, 1, 1, and the cardinalities of the right subtrees are 3, 1. Hence,

$$(81) \quad c_{221}(q) = [5]_q! \frac{q^{3+1}}{[5]_q[3]_q[1]_q^3} = q^4 + 2q^5 + 2q^6 + 2q^7 + q^8.$$

Applying the Schützenberger involution ν to C_I amounts to sending $\mathbf{G}_\sigma$ to $\check{\mathbf{G}}_\sigma = \mathbf{G}_{\omega\sigma\omega}$, so that we can also reformulate Theorem 3.6 as

$$(82) \quad \check{C}_I(X) = \check{\mathfrak{S}}_I^*.$$

COROLLARY 3.11 ([3]). *$\overline{\mathfrak{S}}_I^*$ is the characteristic of an indecomposable 0-Hecke algebra module.*

Proof. The inverses of the permutations occurring in $C_I(A)$ are the linear extensions of a poset (a binary tree in this case), hence form the basis of a 0-Hecke module, see Section 3.9 of [8]. Thus, the commutative image $C_I(X) = \overline{\mathfrak{S}}_I^*$ of $C_I(A)$ in $QSym$ is the characteristic of this module. The same is true of their images by the Schützenberger involution, the poset being now a binary tree turned upside-down. Moreover, these modules are indecomposable, since they are of the form $\mathbf{N}_\sigma$ described in [8, Def. 4.3]. Indeed, the right-comb tree associated with a composition I is the shape of the decreasing tree of the maximal permutation $\omega(I)$ of the descent class I . This permutation (which is sent to $\omega(\bar{I})$ by the Schützenberger involution) spans the (one-dimensional) socle of the module, which must be contained in any submodule, so that no submodule can be a direct summand. $\square$

See [21] or [38] for an introduction to the representation theory of the 0-Hecke algebra.

4. THE DUAL IMMACULATE BASIS

4.1. HALF-SHUFFLES AND **FQSym**. The shuffle product on $\mathbb{K}\langle A \rangle$ can be recursively defined by (52):

$$(83) \quad ua \sqcup vb = (ua \sqcup v)b + (u \sqcup vb)a$$

or symmetrically by

$$(84) \quad au \sqcup bv = a(u \sqcup bv) + b(au \sqcup v),$$

where $a, b \in A$ and $u, v \in A^*$. The half-shuffles are also known as chronological products. Both ways of splitting the shuffle can be used to define a dendriform structure on **FQSym**. In this section, we shall use the second possibility (84) and set

$$(85) \quad au \prec' bv = a(u \sqcup bv), \text{ and } au \succ' bv = b(au \sqcup v).$$

If γ is a linear combination of some permutations ρ , we write for short $\mathbf{F}_\gamma$ for the same linear combination of the $\mathbf{F}_\rho$. On **FQSym**, we set, for $\sigma \in \mathfrak{S}_k$ and $\tau \in \mathfrak{S}_l$

$$(86) \quad \mathbf{F}_\sigma \prec' \mathbf{F}_\tau = \mathbf{F}_{\sigma \prec' \tau[k]}, \text{ and } \mathbf{F}_\sigma \succ' \mathbf{F}_\tau = \mathbf{F}_{\sigma \succ' \tau[k]}.$$

Here, $\succ'$ coincides with Grinberg's $\succ$, which we will denote by $\succ_G$ to avoid confusions.

LEMMA 4.1. *For any two words u and v ,*

$$(87) \quad u \prec' v = \sum_{v_1 v_2 = v} (-1)^{|v_1|} (\bar{v}_1 u) \sqcup v_2,$$

where $\bar{w}$ denotes the mirror image of a word w .

Proof. By definition

$$(88) \quad au \prec' bv = au \sqcup bv - au \succ' bv,$$

and since

$$(89) \quad au \succ' bv = bau \prec' v,$$

the result follows by induction. $\square$

For example,

$$(90) \quad 1234 \prec' 567 = 1(234 \sqcup 567) = 1234 \sqcup 567 - 51234 \sqcup 67 + 651234 \sqcup 7 - 7651234.$$

In **FQSym**, this implies

$$(91) \quad \mathbf{F}_\sigma \prec' \mathbf{F}_\tau = \sum_{uv = \tau[k]} (-1)^{|u|} \mathbf{F}_{(\bar{u} \cdot \sigma) \sqcup v}.$$

For example,

$$(92) \quad \mathbf{F}_{2143} \prec' \mathbf{F}_{312} = \mathbf{F}_{2143 \sqcup 756} - \mathbf{F}_{72143 \sqcup 56} + \mathbf{F}_{572143 \sqcup 6} - \mathbf{F}_{6572143}.$$

4.2. DESCENTS IN HALF-SHUFFLES. For $w \in A^*$, let $\text{alph}(w) \subseteq A$ be the set of letters occurring in w . The following property appears as Lemma 4.1 in [30]:

LEMMA 4.2. *If $\text{alph}(u) \cap \text{alph}(v) = \emptyset$, then*

$$(93) \quad \langle u \sqcup v \rangle = \langle u \rangle \langle v \rangle,$$

where the linear map $\langle \rangle$ is defined by $\langle u \rangle := F_{C(u)}$, where $C(u)$ denotes the descent composition of the word u . In particular, the descents of the elements of a shuffle on disjoint alphabets depend only on the descents of the initial elements.

There is a refined statement for the dendriform half-products [30, Thm. 4.2] that we adapt to our half-products:

THEOREM 4.3. *Let $u = u_1 \cdots u_k$ and $v = v_1 \cdots v_\ell$ be two nonempty words of respective lengths k and ℓ . If $\text{alph}(u) \cap \text{alph}(v) = \emptyset$, then*

$$(94) \quad \langle u \prec' v \rangle = \langle \sigma \prec' \tau \rangle$$

where $\sigma = \text{std}(u)$ and $\tau = \text{std}(v)[k]$ if $u_1 < v_1$, and $\sigma = \text{std}(u)[\ell]$ and $\tau = \text{std}(v)$ if $u_1 > v_1$.

For example, we have

$$(95) \quad \begin{aligned} \langle 14 \prec' 23 \rangle &= \langle 1423 + 1243 + 1234 \rangle = F_{22} + F_{31} + F_4 \\ \langle 12 \prec' 34 \rangle &= \langle 1234 + 1324 + 1342 \rangle = F_4 + F_{22} + F_{31}, \end{aligned}$$

whereas

$$(96) \quad \begin{aligned} \langle 24 \prec' 13 \rangle &= \langle 2413 + 2143 + 2134 \rangle = F_{22} + F_{121} + F_{13} \\ \langle 34 \prec' 12 \rangle &= \langle 3412 + 3142 + 3124 \rangle = F_{22} + F_{121} + F_{13}. \end{aligned}$$

4.3. PROJECTION ONTO $QSym$. Let $\pi : \mathbf{FQSym} \rightarrow QSym$ be the canonical projection sending $\mathbf{F}_\sigma$ to $F_{C(\sigma)}$. Then π is compatible with the products of both structures, and we can define half-products $\prec'$ and $\succ'$ on $QSym$ in such a way that π will be compatible with the half-products as well. This follows from an even more general trivial property. Let us consider σ and σ' having the same descents and τ and τ' also. Any word w in the shifted shuffle $\sigma \sqcup \tau = \sigma \sqcup \tau[k]$ ($\sigma \in \mathfrak{S}_k$) is characterized by the sequence of positions of the letters of σ . Then the word w' in $\sigma' \sqcup \tau'$ with the same sequence of positions of the letters of σ' has obviously the same descents as w . Since it is true for all elements, it is in particular true when one sums over subsets of the shuffle, e.g., $\prec'$ and $\succ'$. Thus, if $C(\sigma) = I$ and $C(\tau) = J$, we can define in $QSym$

$$(97) \quad F_I \prec' F_J := \pi(\mathbf{F}_\sigma \prec' \mathbf{F}_\tau).$$

For example,

$$(98) \quad \mathbf{F}_{21} \prec' \mathbf{F}_{132} = \mathbf{F}_{21354} + \mathbf{F}_{23154} + \mathbf{F}_{23514} + \mathbf{F}_{23541},$$

so that

$$(99) \quad F_{11} \prec' F_{21} = F_{131} + F_{221} + F_{32} + F_{311},$$

which could have been computed as well from

$$(100) \quad \mathbf{F}_{21} \prec' \mathbf{F}_{231} = \mathbf{F}_{21453} + \mathbf{F}_{25153} + \mathbf{F}_{24513} + \mathbf{F}_{24531}.$$

Applying Lemma 4.2, we can project (91) to $QSym$. If the descent composition of u is H and that of σ is I , the descent composition of $\bar{u}$ is the conjugate composition $H^\sim$, and if $u_1 > \sigma_1$, the descent composition of $\bar{u} \cdot \sigma$ is $H^\sim \cdot I$. We have therefore

$$(101) \quad F_I \prec' F_J = \sum_{J \in \{HK, H \triangleright K\}} (-1)^{|H|} F_{H^\sim \cdot I} F_K,$$

where for two compositions $H = (h_1, \dots, h_r)$ and $K = (k_1, \dots, k_s)$

$$(102) \quad HK = (h_1, \dots, h_r, k_1, \dots, k_s) \text{ and } H \triangleright K = (h_1, \dots, h_r + k_1, \dots, k_s).$$

For example,

$$(103) \quad \mathbf{F}_{21} \prec' \mathbf{F}_{132} = \mathbf{F}_{21\sqcup 354} - \mathbf{F}_{321\sqcup 54} + \mathbf{F}_{5321\sqcup 4} - \mathbf{F}_{45321},$$

so that

$$(104) \quad \pi(\mathbf{F}_{21} \prec' \mathbf{F}_{132}) = F_{11}F_{21} - F_{111}F_{11} + F_{1111}F_1 - F_{2111},$$

corresponding to the decompositions $J = \emptyset \cdot 21$, $1 \triangleright 11$, $2 \cdot 1$, and $21 \cdot \emptyset$.

Since the antipode S of $QSym$ is given by

$$(105) \quad S(F_H) = (-1)^{|H|} F_{H^\sim},$$

and the coproduct by

$$(106) \quad \Delta(F_J) = \sum_{J \in \{HK, H \triangleright K\}} F_H \otimes F_K$$

we obtain in this way [14, Detailed version (ancillary file), Thm. 3.15]:

THEOREM 4.4. *Let the $\prec'$ product on $QSym$ be defined by (97). Then, for $f, g \in QSym$,*

$$(107) \quad f \prec' g = \sum_{(g)} (S(g_{(1)}) \bullet f) g_{(2)}$$

where $F_I \bullet F_J := F_{I \cdot J}$ and $\Delta g = \sum_{(g)} g_{(1)} \otimes g_{(2)}$.

For example, applying π to (92), we obtain

$$(108) \quad F_{121} \prec' F_{12} = F_{121}F_{12} - F_{1121}F_2 + F_{2121}F_1 - F_{12121}.$$

4.4. QUASI-DIFFERENTIAL OPERATORS. Theorem 4.4 can be reformulated in terms of quasi-differential operators, as in [14]. According to [20, Def. 4.5], for $f \in QSym$,

$$(109) \quad f(X - Y) = \sum_I S(F_I)(Y) \cdot R_I^\perp(f)(X),$$

where the quasi-differential operator $R_I^\perp$ is defined as in [14], i.e., as the adjoint of the linear map $f \mapsto R_I f$. Indeed, recall that $f(X - Y)$ is defined as $f((-Y) \hat{+} X)$, where $\hat{+}$ is the ordinal sum of alphabets, $f(-Y) = S(f)(Y)$. Now,

$$(110) \quad f(X \hat{+} Y) = \sum_{J, K} \langle \Delta f, R_J \otimes R_K \rangle F_J(X) F_K(Y)$$

$$(111) \quad = \sum_{J, K} \langle f, R_J R_K \rangle F_J(X) F_K(Y)$$

$$(112) \quad = \sum_{J, K} \langle R_J^\perp f, R_K \rangle F_J(X) F_K(Y)$$

$$(113) \quad = \sum_J F_J(X) \sum_K \langle R_J^\perp f, R_K \rangle F_K(Y)$$

$$(114) \quad = \sum_J F_J(X) (R_J^\perp f)(Y).$$

Replacing X, Y by $-Y, X$, this becomes

$$(115) \quad f(-Y \hat{+} X) = \sum_J F_J(-Y) (R_J^\perp f)(X) = \sum_J S(F_J)(Y) \cdot R_J^\perp(f)(X),$$

We can therefore rewrite (107) as

$$(116) \quad f \prec' g(X) = [g(X - Y) \bullet_Y f(Y)]_{Y=X}.$$

For example

$$(117) \quad F_{12}(X - Y) = F_{12}((-Y) \hat{+} X) \\ = F_{12}(-Y) + F_{11}(-Y)F_1(X) + F_1(-Y)F_2(X) + F_{12}(X)$$

$$(118) \quad = -F_{12}(Y) + F_2(Y)F_1(X) - F_1(Y)F_2(X) + F_{12}(X).$$

Taking the $\bullet$ product with $F_{121}(Y)$, we obtain

$$(119) \quad F_{12}(X - Y) \bullet F_{121}(Y) \\ = -F_{12121}(Y) + F_{2121}(Y)F_1(X) - F_{1121}(Y)F_2(X) + F_{121}(Y)F_{12}(X),$$

and setting $Y = X$, we recover (108).

Similarly, we have for the right product

$$(120) \quad u \succ' v = \sum_{u_1 u_2 = u} (-1)^{|u_1|} u_2 \sqcup \overline{u_1} v.$$

Thus, on $QSym$, if one defines $\blacktriangleright$ by $F_I \blacktriangleright F_J = F_{I \blacktriangleright J}$, then

$$(121) \quad f \succ' g = \sum_{(f)} (S(f_{(1)}) \blacktriangleright g) f_{(2)}.$$

This is precisely [14, Thm. 3.7]. For example,

$$(122) \quad \mathbf{F}_{132} \succ' \mathbf{F}_{21} = \mathbf{F}_{132 \sqcup 54 - 32 \sqcup 154 + 2 \sqcup 3154 - 23154},$$

which projects onto

$$(123) \quad F_{21} \succ' F_{11} = F_{21} F_{11} - F_{11} F_{21} + F_1 F_{121} - F_{221} = F_{131} + F_{1121} + F_{122} + F_{1211}.$$

4.5. STANDARD DENDRIFORM STRUCTURES. With the usual definitions

$$(124) \quad ua \prec vb = (u \sqcup vb)a, \quad ua \succ vb = (ua \sqcup v)b,$$

the half-shuffle identity becomes

$$(125) \quad u \prec v = \sum_{v_1 v_2 = v} (-1)^{|v_2|} u \overline{v_2} \sqcup v_1$$

which induces an operation on $QSym$ defined by

$$(126) \quad F_I \prec F_J = \sum_{J \in \{HK, H \blacktriangleright K\}} (-1)^{|K|} F_{I \blacktriangleright K} F_H,$$

or equivalently,

$$(127) \quad f \prec g = \sum_{(g)} g_{(1)} (f \blacktriangleright S(g_{(2)})).$$

For example,

$$(128) \quad \mathbf{F}_{21} \prec \mathbf{F}_{132} = \mathbf{F}_{35421} + \mathbf{F}_{35241} + \mathbf{F}_{32541} + \mathbf{F}_{23541}$$

and

$$(129) \quad F_{11} \prec F_{21} = F_{2111} + F_{221} + F_{1211} + F_{311}.$$

Then,

$$(130) \quad F_I \prec F_J = F_I(Y) \blacktriangleright_Y F_J(X - Y)|_{Y=X}.$$

For example,

$$(131) \quad F_{21}(X - Y) = F_{21}(X) - F_1(Y)F_2(X) + F_2(Y)F_1(X) - F_{21}(Y)$$

and

$$(132) \quad F_{11}(Y) \blacktriangleright_Y F_{21}(X - Y) \\ = F_{11}(Y)F_{21}(X) - F_{12}(Y)F_2(X) + F_{13}(Y)F_1(X) - F_{131}(Y)$$

so that

$$(133) \quad F_{11} \prec F_{21} = F_{11}F_{21} - F_{12}F_2 + F_{13}F_1 - F_{131}.$$

For the right product, we have

$$(134) \quad u \succ v = \sum_{u_1 u_2 = u} (-1)^{|u_2|} u_1 \sqcup v \overline{u_2},$$

and on $QSym$,

$$(135) \quad f \succ g = \sum_{(f)} f_{(1)} (g \bullet S(f_{(2)})).$$

For example,

$$(136) \quad \mathbf{F}_{21} \succ \mathbf{F}_{231} = \mathbf{F}_{21 \sqcup 453 - 2 \sqcup 4531 + 45312}$$

which yields on $QSym$

$$(137) \quad F_{11} \succ F_{21} = F_{11}F_{21} - F_1F_{211} + F_{212} = F_{131} + F_{122} + F_{221} + F_{32} + F_{1121} + F_{212}.$$

4.6. GRINBERG'S OPERATIONS. In [14], a left product $\prec_G$ on $QSym$ is induced from an operation on monomials. This operation is the commutative image of the left tridendriform product on words defined in [28] (with the use of min instead of max, so that we shall consistently denote it by $\prec'$), and amounts to taking the canonical projection $\pi : \mathbf{WQSym} \rightarrow QSym$ of the tridendriform product of $\mathbf{WQSym}$:

$$(138) \quad M_I \prec_G M_J := \pi(\mathbf{M}_u \prec' \mathbf{M}_v)$$

where u, v are any packed words of evaluation I, J .

For example, to evaluate $F_{11} \prec_G F_{21}$, we compute $M_{11} \prec_G (M_{21} + M_{111})$, hence $\mathbf{M}_{21} \prec' (\mathbf{M}_{132} + \mathbf{M}_{121})$:

$$\begin{aligned} \mathbf{M}_{21} \prec' \mathbf{M}_{132} &= \mathbf{M}_{21243} + \mathbf{M}_{21354} + \mathbf{M}_{31243} + \mathbf{M}_{41243} + \mathbf{M}_{51243} + \mathbf{M}_{41253} + \mathbf{M}_{31254}, \\ \mathbf{M}_{21} \prec' \mathbf{M}_{121} &= \mathbf{M}_{21232} + \mathbf{M}_{31212} + \mathbf{M}_{21343} + \mathbf{M}_{31242} + \mathbf{M}_{41232} \end{aligned}$$

so that

$$(139) \quad \begin{aligned} F_{11} \prec_G F_{21} &= 3M_{1211} + 2M_{1121} + M_{1112} + M_{122} + M_{131} + 4M_{1111} \\ &= F_{131} + F_{122} + F_{1121} + F_{1211}, \end{aligned}$$

which is different from all previous examples such as (99).

This operation can then be lifted to $\mathbf{FQSym}$ as

$$(140) \quad \mathbf{F}_\sigma \prec_G \mathbf{F}_\tau := \mathbf{F}_{\sigma[l] \prec' \tau},$$

where $l = |\tau|$, and $au \prec' bv$ is defined as $a(u \sqcup bv)$. Then Equation (87) yields [14, Thm. 3.7]

$$(141) \quad F_I \prec_G F_J = \sum_{J \in \{HK, H \triangleright K\}} (-1)^{|H|} F_{H \sim \triangleright I} F_K.$$

For example,

$$(142) \quad \mathbf{F}_{21} \prec_G \mathbf{F}_{132} = \mathbf{F}_{54132} + \mathbf{F}_{51432} + \mathbf{F}_{51342} + \mathbf{F}_{51234},$$

and one can check that

$$(143) \quad 54 \prec' 132 = 54 \sqcup 132 - 154 \sqcup 32 + 3154 \sqcup 2 - 23154,$$

so that

$$(144) \quad F_{11} \prec_G F_{21} = F_{11}F_{21} - F_{21}F_{11} + F_{121}F_1 - F_{221}.$$

Alternatively, we can describe $\prec_G$ as

$$(145) \quad \mathbf{F}_\sigma \prec_G \mathbf{F}_\tau = \mathbf{F}_\tau \succ' \mathbf{F}_\sigma.$$

On $QSym$, this translates as

$$(146) \quad f \prec_G g = \sum_{(g)} g_{(2)} (S(g_{(1)}) \blacktriangleright f)$$

which is now [14, Thm. 3.7] in its original form.

Grinberg's expression of the dual immaculate basis can now be restated as

$$(147) \quad \mathfrak{S}_I^* = (\cdots (F_{i_r} \succ' F_{i_{r-1}}) \succ' \cdots) \succ' F_{i_1}.$$

For example,

$$(148) \quad \mathfrak{S}_{221}^* = (F_1 \succ' F_2) \succ' F_2 = (F_{12} + F_{21}) \succ' F_2.$$

NOTE 4.5. On **FQSym**, the operation $\prec_G$ is not a left dendriform product in the usual sense, as it is in fact a flipped right product. The $\prec'$ operation on **WQSym** which induces it does not preserve the standard **FQSym** subalgebra of **WQSym**.

Finally, it is also possible to deduce Theorem 3.6 from Grinberg's results. The following argument has been suggested by an anonymous referee.

Let $f \mapsto \bar{f}$ be the anti-involution of **FQSym** defined by $\bar{F}_\sigma = F_{\omega\sigma\omega}$, and denote by $\pi : \mathbf{FQSym} \rightarrow QSym$ the canonical projection $\pi(F_\sigma) = F_{C(\sigma)}$. As already observed, $\pi(\bar{f}) = \overline{\pi(f)}$. It is easy to see that

$$(149) \quad \overline{a \prec b} = \bar{b} \succ_G \bar{a} \quad \text{for all } a, b \in \mathbf{FQSym}.$$

Moreover, in [14, §6], it is said that

$$(150) \quad \pi(a) \prec_G \pi(b) = \pi(a \succ b) \quad \text{for all } a, b \in \mathbf{FQSym}.$$

Now, let $I = (i_1, i_2, \dots, i_r)$ be a composition. Then, [14, Cor. 4.7] shows that

$$\begin{aligned} \mathfrak{S}_I^* &= h_{i_1} \prec_G (h_{i_2} \prec_G (\dots (h_{i_r} \prec_G 1) \dots)) \\ &= h_{i_1} \prec_G (h_{i_2} \prec_G (\dots (h_{i_{r-1}} \prec_G h_{i_r}) \dots)) \\ &= \pi(S_{i_1}) \prec_G (\pi(S_{i_2}) \prec_G (\dots \prec_G \pi(S_{i_{r-1}}) \prec_G \pi(S_{i_r})) \dots) \\ &\quad (\text{since } h_k = \pi(S_k) \text{ for all } k) \\ &= \pi(((\dots (S_{i_r} \succ_G S_{i_{r-1}}) \succ_G \dots) \succ_G S_{i_2}) \succ_G S_{i_1}) \\ &\quad (\text{by applying (150) many times}) \\ &= \pi(\overline{((\dots (\bar{S}_{i_r} \succ_G \bar{S}_{i_{r-1}}) \succ_G \dots) \succ_G \bar{S}_{i_2}) \succ_G \bar{S}_{i_1}}) \\ &\quad (\text{since } \bar{S}_k = S_k) \\ &= \pi(\overline{S_{i_1} \prec (S_{i_2} \prec (\dots \prec (S_{i_{r-1}} \prec S_{i_r}) \dots))}) \\ &\quad (\text{by applying (149) many times}) \\ &= \pi(\overline{C_I(A)}) \quad \text{as seen in the proof of Lemma 3.1} \\ &= \overline{\pi(C_I(A))} \\ &= \overline{C_I(X)}. \end{aligned}$$

Hence, Theorem 3.6 follows from [14, Cor. 4.7].

5. HOPF ALGEBRAS OF SET PARTITIONS

We have seen that the Bell polynomial B_n can be identified with the formal sum of permutations avoiding $21-3$ (up to the Y^I which can be reconstructed from the descent sets). This raises the question of the existence of a Hopf subalgebra or quotient of **FQSym** whose bases are naturally labeled by these permutations.

The most obvious Hopf algebra of set partitions is **WSym**, or symmetric functions in noncommuting variables (not to be confused with noncommutative symmetric functions **Sym**). In [17], a quotient of **WSym** isomorphic to **Sym** and a *QSym* subalgebra of its dual are related to Bell polynomials. In [5], analogues of the Bell polynomials in various other Hopf algebras are considered.

5.1. THE BELL HOPF ALGEBRA. The Hopf algebra **WSym** is cocommutative. Quite often, combinatorial objects also admit a self-dual Hopf algebra structure. Such an algebra has been constructed by Rey [34, 35] for set partitions from the Burstein–Lankham correspondence, a combinatorial construction derived from the patience sorting algorithm. More precisely, the Bell classes of Rey are indexed by permutations avoiding $23-1$, and these are their minimal elements (for the weak order). We can modify the construction so as to have classes whose maximal elements avoid $21-3$ as follows.

Let A be a totally ordered alphabet. The (modified) Bell congruence on A^* is generated by the relations⁽⁴⁾

$$(151) \quad buca \equiv buac \quad \text{if } a < b < c \text{ and all letters of } u \text{ are smaller than } b.$$

This is a refinement of the reverse sylvester congruence, which is defined by the same relations without restriction on u .

As for the sylvester or reverse sylvester congruences, we have:

THEOREM 5.1. *The Bell equivalence classes of permutations, (i.e., equivalence classes of words with no equal letters under the Bell congruence) are intervals of the right weak order on the symmetric group. These intervals consist of the linear extensions of posets which will be explicitly described below, and the maximal elements of these intervals are the $21-3$ -avoiding permutations.*

Identifying set partitions π with their representatives $\hat{\pi}^b$ as $21-3$ -avoiding permutations, we set

$$(152) \quad P_\pi = \sum_{\sigma \equiv \pi} \mathbf{F}_\sigma.$$

THEOREM 5.2 (Rey [35]). *The P_π span a Hopf subalgebra of **FQSym**.*

5.2. THE POSET OF SET PARTITIONS. Since the long version of Rey’s paper [35] has never been published, we shall provide detailed proofs of his results (in our modified version), to which we add the explicit description of the posets.

5.2.1. *From permutations to set partitions.* Let us first define an insertion algorithm. This is a rewriting of the Patience Sorting Algorithm defined by Burstein and Lankham adapted to our setting, which amounts to applying some trivial involutions on words. Precisely, if we invert the total order of the alphabet, our algorithm becomes Algorithm 3.1 of [34], our blocks being Rey’s piles read downwards.

The first object that we create is a set partition, that we shall regard as ordered in such a way that the maximal elements of the blocks decrease from left to right.

Let $w = w_1 \dots w_n$ be a word with no repeated letters over a totally ordered alphabet. Put $S = \emptyset$. Then, read w from left to right and for each letter w_i do

- Step 1: Let s be the block of S whose maximal element is smaller than (or equal to) w_i and is greater than all other maximal elements smaller than w_i .
- Step 2: If s does not exist, add $\{w_i\}$ to S . If s exists, insert w_i into it.

The result of this algorithm will be denoted by $\text{PSA}(w)$.

We shall display the blocks of S as columns, increasing from top to bottom (so that an element is inserted at the bottom of its column), the columns being ordered from left to right with their maximal elements in decreasing order.

⁽⁴⁾As observed by Grinberg (private communication), an alternative description is $bcu \equiv buc$ for $b < c$ if all letters of u are $< b$.

For example, the insertion of $(3, 1, 2, 6, 4, 5, 7)$ follows the steps:

$$S = \emptyset \rightarrow S = \boxed{3} \rightarrow S = \boxed{3} \boxed{1} \rightarrow S = \boxed{3} \boxed{1} \boxed{2} \rightarrow S = \boxed{3} \boxed{1} \boxed{6} \boxed{2} \\ \rightarrow S = \begin{array}{|c|c|} \hline 3 & 1 \\ \hline 6 & 2 \\ \hline 4 & \\ \hline \end{array} \rightarrow S = \begin{array}{|c|c|} \hline 3 & 1 \\ \hline 6 & 2 \\ \hline 4 & \\ \hline 5 & \\ \hline \end{array} \rightarrow S = \begin{array}{|c|c|} \hline 3 & 1 \\ \hline 6 & 2 \\ \hline 7 & 4 \\ \hline 5 & \\ \hline \end{array}$$

5.2.2. *From set partitions to posets.* Now, starting from a set partition S , we shall build a poset P on the ground set $\{1, 2, \dots, n\}$ whose relation $>_P$ is generated by the following requirements: order S as above, and, for any element x of a block s of S , write $x >_P x'$ where x' is the greatest element smaller than x in s and write $x >_P x''$ where x'' is the smallest element greater than x in the block immediately to the left of s in S (if such a block and such an element exist). The transitive closure of $>_P$ defines a poset which will be denoted by $P(S)$ or by $P(w)$ if S is the result of the (modified) patience sorting algorithm applied to w . Note that by removing the edges of the Hasse diagram of $P(S)$ where the element above is greater than the element below, one recovers S itself. Hence it makes sense to refer to the columns of S as the corresponding columns of the poset $P(S)$. For w in P , we shall write $C(w)$ for its column.

As usual with posets, we shall only represent the covering relations. For example, starting with the set S computed before, we get (orienting the Hasse diagrams upside-down, with minimal elements at the top):

$$(153) \quad \begin{array}{c} 3 \\ \swarrow \quad \searrow \\ 6 \quad 1 \\ \swarrow \quad \downarrow \quad \searrow \\ 7 \quad 2 \\ \swarrow \quad \downarrow \\ 4 \\ \swarrow \\ 5 \end{array}$$

Indeed, the first column of S is $(3, 6, 7)$ and $6 > 3$ and $7 > 6$. Now, on the second column we have $5 > 4 > 2 > 1$ and the relations between these elements and the first column are: $1 >_P 3$, $2 >_P 3$, $4 >_P 6$, and $5 >_P 6$, whence the Hasse diagram above.

Starting with $S = (6, 10, 11|2, 4, 8, 9|3, 7|5|1)$, one gets

$$S = \begin{array}{|c|c|c|c|c|} \hline 6 & 2 & 3 & 5 & 1 \\ \hline 10 & 4 & 7 & & \\ \hline 11 & 8 & & & \\ \hline & 9 & & & \\ \hline \end{array}$$

and

$$(154) \quad P(S) = \begin{array}{c} 6 \\ \swarrow \quad \searrow \\ 10 \quad 2 \\ \swarrow \quad \downarrow \quad \searrow \\ 11 \quad 4 \\ \swarrow \quad \downarrow \quad \searrow \\ 8 \quad 3 \\ \swarrow \quad \downarrow \quad \searrow \\ 9 \quad 7 \\ \swarrow \quad \searrow \\ 5 \\ \searrow \\ 1 \end{array}$$

Note that in this representation, the columns of $P(S)$ are the straight lines going from south-west to north-east.

5.3. PROOFS. We shall now prove Theorem 5.1: all elements in a given Bell class have the same poset $P(w) = P(\text{PSA}(w))$, and the linear extensions (taken from top to bottom in our representation) of such a poset give elements of the same Bell class. Hence being in the same Bell class is equivalent to having the same poset.

5.3.1. *All elements in a given Bell class have the same poset.* First, let us prove that all elements in a given Bell class have the same poset, or, equivalently, the same result by the PSA algorithm. We only need to prove this for two elements w and w' obtained from one another by a single rewriting rule. So, let us consider $w = vbuaac$ and $w' = vbucac$ where all letters of u are smaller than b . When b is inserted, it is the bottommost element of its column, and it remains so during the insertion of all u , since all the letters of u are smaller than b . Now, a letter $c > b$ is necessarily inserted into a column to the left of $C(b)$ or into it, independently of the insertion of a . Meanwhile, a letter a smaller than b is necessarily inserted into a column strictly to the right of $C(b)$ (whether or not c has already been inserted). Thus, the insertions of c and a do not interfere with each other. So w and w' satisfy $\text{PSA}(w) = \text{PSA}(w')$.

Note that the condition that all letters of u are smaller than b is necessary to ensure that c and a cannot both be inserted in the same column, which would prevent w and w' from yielding the same result by the modified patience sorting algorithm.

5.3.2. *All linear extensions of a poset are Bell congruent.* Let us now prove that all linear extensions of a poset $P(\sigma)$ are Bell congruent to σ .⁽⁵⁾ First note that the poset obtained from a permutation σ has a unique minimal element m at its top: indeed, it is easy to see that whenever $p < q$, each element of the q th column is $>_P$ to the smallest element of the p th column. Now, σ is a linear extension of it, since when we insert a new letter r , we do not get a new covering relation of the form $s >_P r$.

One can thus rebuild the corresponding set partition $\text{PSA}(\sigma)$ since each column of $P(\sigma)$ is a saturated chain of the poset $P(\sigma)$, and conversely, if we remove all edges of the form $u >_P v$ satisfying $u < v$ from the Hasse diagram of $P(\sigma)$, then only these saturated chains remain. Let us define a *Bell poset* as a poset $P(S)$ for a set partition S of some finite set of integers, not necessarily $\{1, 2, \dots, n\}$. It is easy to see that removing a maximal element from a Bell poset yields a Bell poset, which implies that any down-closed subset of a Bell poset is again a Bell poset. So, let us now consider two values $a < c$, both maximal elements of P , and let P' be the poset obtained from P by removing a and c . By induction on n , we can assume that all linear extensions of P' are Bell-congruent with one another. To prove that the same holds for P , we only need to prove that there exists one linear extension v of P' such that $v \cdot ac \equiv v \cdot ca$: indeed, all linear extensions of a poset can be reached from one another by such exchanges.

First, note that $C(a)$ is to the right of $C(c)$ since they are both maximal elements of their column. Let us prove that there exists a linear extension of P' that ends with a letter b such that $a < b < c$, possibly followed by letters smaller than a . We shall use twice a very simple observation: if x is the last letter of a column, then there are linear extensions of the associated poset where x is only followed by letters smaller than itself. Indeed, the letters that must appear after x in all linear extensions of the poset are letters belonging to columns to the right of $C(x)$, hence all smaller than x .

Now, if $C(c)$ is not the column immediately to the left of $C(a)$, define b as the maximal element of this column. It satisfies $a < b < c$ and all elements after it in

⁽⁵⁾Grinberg (private communication) has proposed another proof, an induction of the length of σ .

the linear extensions of P' are smaller than b , and in fact smaller than a . So there are linear extensions of P' where the rewriting $wca \equiv wac$ is possible. Otherwise, since a and c are both maximal elements of P , they cannot be comparable. Define b as the letter immediately above c in its column. It exists since otherwise a would be connected to c (definition of the posets from the sets of columns). Now, b might not be a maximal element of P' but in any case, the values that are below b in P' are strictly to its right in the partition, hence are all smaller than a , again. So there are linear extensions of P' ending with b and then letters smaller than a . So in both cases, we found a value b allowing to rewrite one linear extension w of P' concatenated to ac with $w \cdot ca$, thus proving that all linear extensions of a poset $P(\sigma)$ are Bell congruent to σ .

5.3.3. Our posets are regular. Now that we have obtained the equivalence between Bell classes and the linear extensions of our posets, it only remains to prove that these posets (regarded as labeled posets in an obvious way) are regular to conclude that the classes are intervals of the weak order [4, Thm. 5.8]. We shall make use of a very simple property: if a value u belongs to a column to the left of a value v , and if $u < v$ then $u <_P v$. Indeed, consider the column C' immediately to the left of $C(v)$. Then v is $>_P$ the smallest value v' greater than itself in C' , hence below all values smaller than itself. Now the same property holds for $v' > v$ on the next column to its left and so on.

Let us now consider two elements x and z such that $x <_P z$, so that $C(x)$ is equal to, or to the left of $C(z)$, which we shall write as $C(x) \preceq C(z)$.

Two cases may appear: $x < z$ or $x > z$. Let us consider the first case and let y be another element of P such that $x < y < z$. In that case, either $C(y) \preceq C(z)$ or $C(y) \succeq C(x)$. In both cases, apply our previous result and conclude that either $x >_P y$ or $y <_P z$. Let us now consider the second case where $x > z$ and let y be another element of P such that $x > y > z$. If $C(y) \preceq C(z)$ or $C(y) \succeq C(x)$, the same argument as before applies. Otherwise, it means that $C(x) \preceq C(y) \preceq C(z)$. But in that case, since there is a saturated chain from x down to z , all elements in between are either comparable to x (if they are below the path) or to z (if they are above the path). So in all cases, we proved that y satisfies either $x <_P y$ or $y <_P z$, hence proving that our posets are regular.

5.3.4. The maximal elements of the Bell classes avoid 21 – 3. Let us finally prove that the maximal elements of the Bell classes avoid the pattern 21 – 3. There are several ways to prove this. One could say for example that the Bell classes are in bijection with set partitions, hence splitting the permutations of size n into as many classes as the number of permutations avoiding 21 – 3. Now, if a permutation σ does not avoid 21 – 3, let us consider such a pattern with letters $ba \dots c$ in σ where the distance between a and c is minimal. Then the letter immediately to the left of c (if it exists: the other case is easy) has to be smaller than b , hence denoted naturally by a' . All letters x between b and a' are necessarily smaller than b , otherwise $ba \dots x \dots a'c$ would have $ba \cdot x$ as a shorter pattern 21 – 3, which would contradict the minimality of the initial one. So we are in the conditions of the Bell congruence, and σ is not a maximal element of its class. So all maximal elements necessarily avoid the pattern 21 – 3. Since both sets, the maximal elements of Bell classes and the permutations avoiding 21 – 3 have same cardinality, they must be equal.

Another proof consists in applying the greedy algorithm that takes a Bell poset as entry and takes the linear extension where at each step one chooses the maximal available value. It is easy to see that these elements necessarily avoid the pattern 21 – 3 and conclude in the same way as before.

Note that the minimal elements are not characterized by pattern avoidance.

5.3.5. *Proof of Theorem 5.2.* As for Theorem 5.2, it follows from a well-known result about algebras defined by congruences, see e.g., Theorem 2.1 of [32] or Chapter 2.1 of [33].
